In general, there is a scarcity of reliable experimental evidence either to support or to contradict these curves. It is expected that they will be verified under controlled conditions by providing some continuous supply of electrons. This supply may come from corona or other localized discharge, ultra-violet rays, x-rays or gamma rays, but hardly from thermal agitation at ambient temperatures common in electronics equipment (usually under 100C). Therefore a somewhat higher breakdown voltage may be fairly certain if such sources are precluded by design. This is especially true of short

pulses such as mentioned above. However, cosmic rays arrive about once per hour per square millimeter, and cannot be stopped by reasonable shielding.

BANDWIDTH NOMOGRAPH

FOR PULSE FILTER NETWORK

Gives minimum bandwidth required for adequate transmission of a periodic rectangular pulse, based on spectral distribution of pulse energy, for any selected efficiency of ideal and R-C filters. Law of diminishing returns applies to bandwidth increases

By B. L. ADAMS and T. M. STOUT

WHEN A PULSE or other signal is applied to a filter with limited bandwidth, the output is a distorted version of the input because some of the frequency components of the signal are attenuated or eliminated. The importance of these components can be measured by the energy which they represent, so it is commonly stated that "such distortion is minimized by the selection of a frequency band sufficiently wide to include nearly all of the total energy of the frequency components."¹

This observation appears frequently in the literature and the principle is well understood. Quantitative application of this idea, however, appears to have been limited to simple cases involving periodic signals or to elegant attacks on the problem of

optimizing performance in the presence of noise.

Periodic Inputs

For a periodic input, the various harmonic components can be found by Fourier analysis; the Fourier series for a number of common periodic waves are readily available in the literature². The power represented by any harmonic can be found by squaring its magnitude, and the combined power of several components is found by addition. In the case of a square wave, for example, the magnitudes vary inversely with n , the order of the harmonic, where $n = 1, 3, 5, \dots$. From this information, one readily determines that the fundamental component of the square wave accounts for 81.1 percent of the total power and

that higher harmonics contribute as shown in the following table:

Highest Harmonic Included	Percent Power
1	81.1
3	90.1
5	93.5
7	95.0
9	96.1
11	96.7
13	97.2

Single-Pulse Inputs

For periodic inputs, such as a rectangular pulse, the frequency components are not distinct but form a continuous spectrum. The relative magnitudes are again determined by Fourier analysis, using the Fourier integral.

The actual signal energy in any portion of the frequency spectrum is found by squaring amplitudes and integrating with

FIG. 1—Transmission efficiency for rectangular pulse input

relation between network

FIG. 3—Nomograph relating efficiency, bandwidth and pulse width. Multiplier k is zero when using seconds for pulse width and cycles per second for bandwidth; any other consistent units may be used, such as $k=3$ for milliseconds and kc or $k=6$ for microseconds and mc

efficiency and quality of pulse reproduction is suggested in Fig. 2, which shows typical pulse responses for ideal and R-C filters. From these pictures one might conclude that 70–75 percent efficiency is a minimum standard, that 90–95 percent is preferable, and that an even higher figure might be better.

In selecting bandwidth, however, consideration should be given to signal-to-noise ratio. In the absence of detailed information, it is probably good policy to use the minimum bandwidth consistent with adequate signal reproduction. In this connection, Fig. 1 shows clearly a law of diminishing returns in increasing bandwidth. For a given pulse width, an increase in efficiency from 90 to 95 percent requires doubling the bandwidth; a further increase to 99 percent requires a further multiplication of bandwidth by five.

Bandwidth Nomograph

Calculations of network bandwidth are simplified by the use of the nomograph shown in Fig. 3. A straight line drawn between points on the upper and lower

scales determines the network efficiency for the given pulse width and bandwidth, for either the ideal filter or R-C filter, depending on which center scale is used. A multiplier is included on the pulse width and bandwidth scales to emphasize that any consistent units may be used, such as seconds and cycles per second, milliseconds and kilocycles or microseconds and megacycles.

Example of Use

As a sample problem, suppose that a 0.5-microsecond pulse is to be transmitted by an ideal filter with an efficiency of 93 percent. Line 1 on the nomograph gives the required bandwidth of three megacycles. According to line 2, somewhat greater bandwidth (4.5 megacycles) is required with an R-C filter.

GAIN-BANDWIDTH NOMOGRAPH

Equations involved in design of single-tuned amplifier circuits are incorporated in one large nomograph to speed up design calculations. Shows overall effect of varying the parameters when seeking the most economical tube arrangement for desired gain and bandwidth

THE design of vacuum-tube amplifiers involves determining the maximum gain and/or bandwidth using the most economical tube arrangement. The most practical first-approximation calculation for single-tuned circuits such as cascaded synchronously tuned i-f stages was found to be $G_m/2\pi C_i$, and the nomograph on the following page was therefore based on this ratio. The nomograph encompasses all of the interdependent equations used in amplifier design, hence shows the effect of variations in each parameter on the others.

Practical values of G_m and C_i that include the effect of the coupling networks can be found by taking approximately 85 percent of the maximum G_m and 160 percent of the value of C_i given in tube manufacturer's data. This makes the usable gain-bandwidth about 53 percent of the ideal, or roughly one-half. This relationship is found in Table I.

The nomograph solves the following equations:

$$Q = f_o/B \quad (1)$$

$$A = G_m \times R_L \quad (2)$$

$$AB = A \times B \quad (3)$$

$$AB = G_m/2\pi C_i \quad (4)$$

$$B = 1/2\pi C_i R_L \quad (5)$$

$$A_{max} = 1/2\pi f_o C_{GP} R_L \quad (6)$$

where $Q = R \omega C =$ circuit quality, $f_o =$ circuit resonant frequency, $B =$ 3-db bandwidth, $A =$ stage gain, $G_m =$ tube

By CHESTER W. YOUNG

transconductance, $R_L =$ total damping resistance, $C_i =$ total shunt capacitance, $A_{max} =$ maximum usable gain, and $C_{GP} =$ total effective grid-plate capacitance.

Since the bandwidth between two 3-db frequencies of a tuned circuit is equal to the 3-db frequency of a parallel or series R-C circuit, the nomograph can be used also for video types of circuits. Also, as Eq. 5 states that bandwidth is independent of L , the nomograph ignores L . Use

Table I—Examples of Ideal and Practical Tube Capacitances

IDEAL				
Tube Type	C_o $\mu\mu f$	C_p $\mu\mu f$	C_i $\mu\mu f$	G_m/C_i mc
6AC7	11.0	5.0	16.0	562
6AK5	4.0	2.8	6.8	750
PRACTICAL				
Tube Type	C_{in} $\mu\mu f$	C_{out} $\mu\mu f$	C_i $\mu\mu f$	G_m/C_i mc
6AC7	17.0	8.0	25.0	312
6AK5	6.7	4.4	11.1	378

of this nomograph is best illustrated by an example.

If the known values are $f_o = 30$ mc, $B = 1$ mc, $C_i = 16 \mu\mu f$, $G_m = 5,000$, and $C_{OP} = 0.0082 \mu\mu f$, find the values of Q , AB , A , R_L and A_{max} .

Step 1: Align points $f_o = 30$ mc and $B = 1$ mc, and read $Q = 30$.

Step 2: Align points $C_i = 16 \mu\mu f$ and $G_m = 5,000$, and read $AB = 50$ mc.

Step 3. Align $AB = 50$ mc and $B = 1$ mc, and read $A = 50$.

Step 4: Align $A = 50$ and $G_m = 5,000$, and read $R_L = 10,000$.

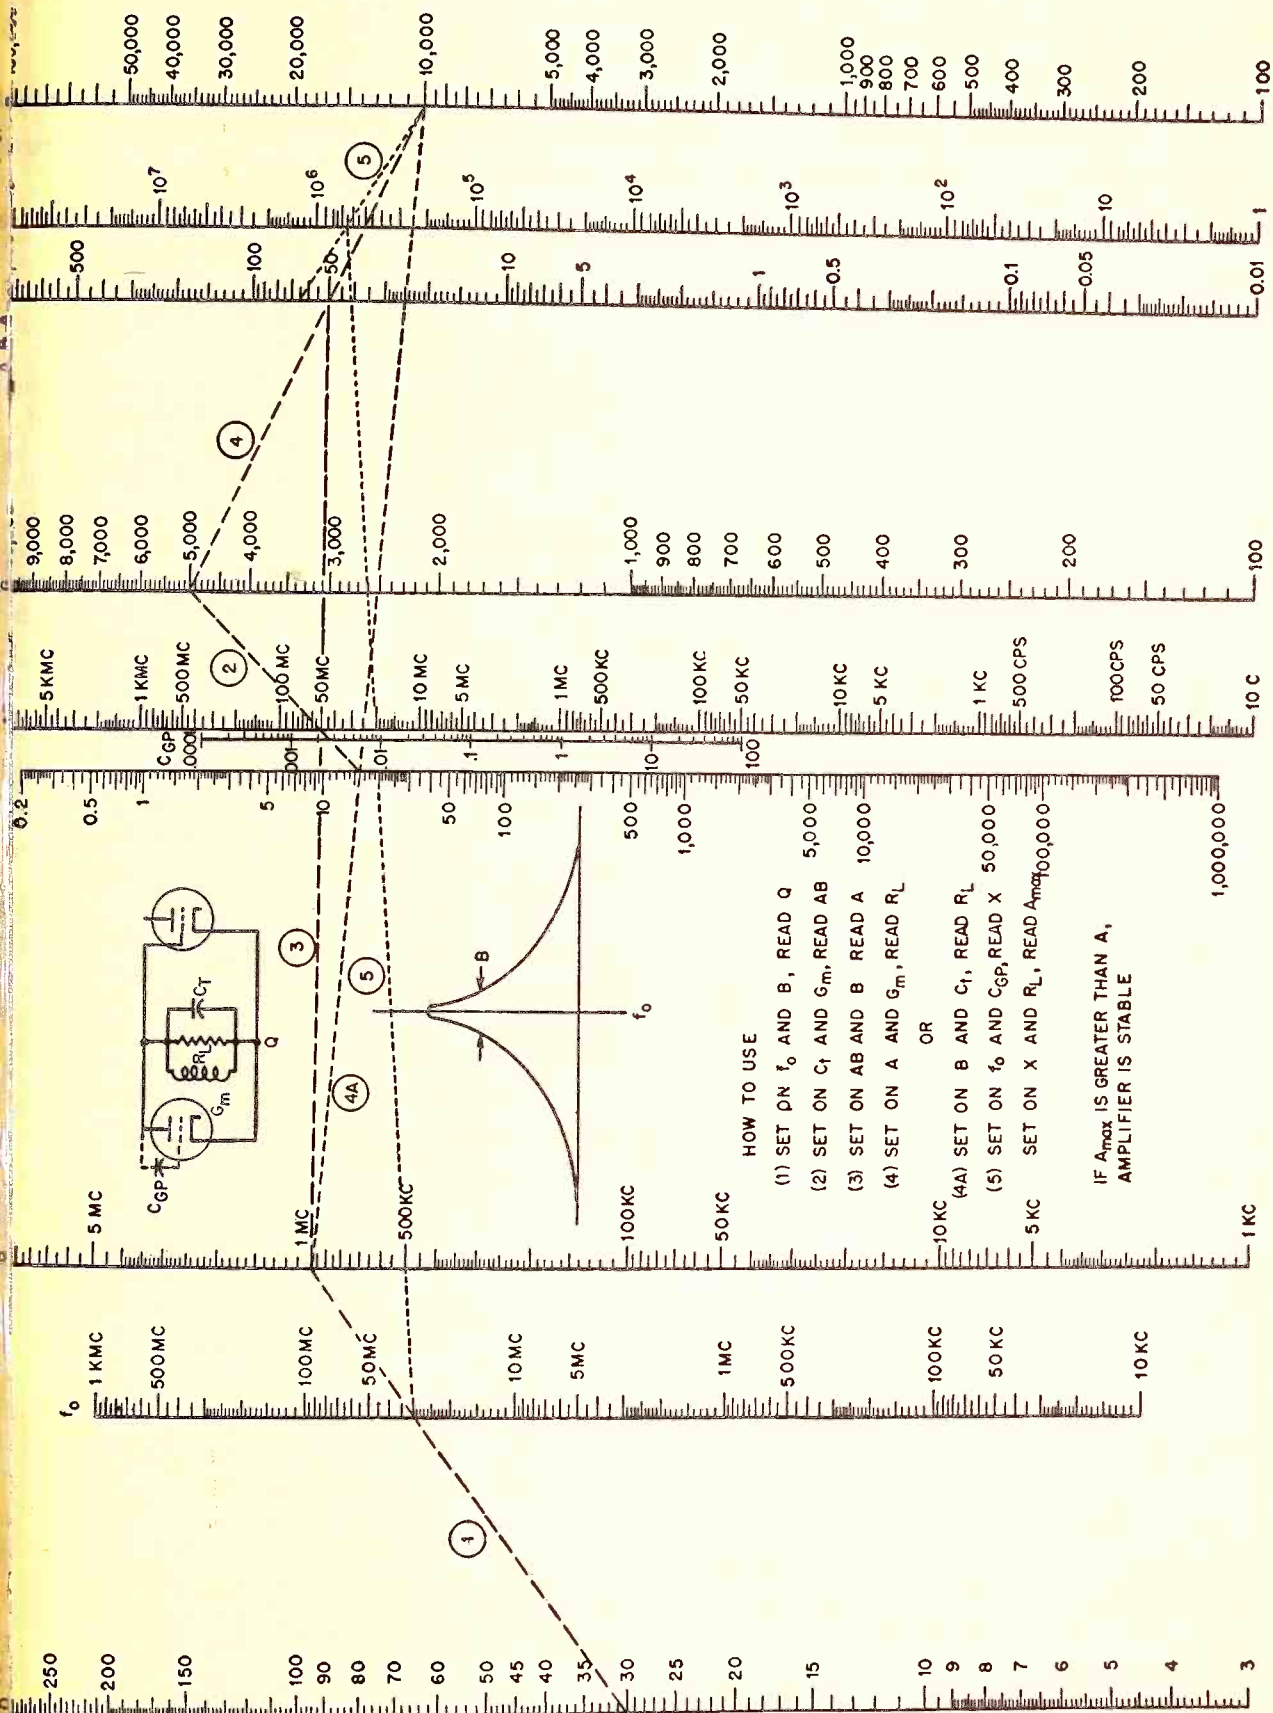

Step 4 (alternate): Since the loading resistance is directly related to bandwidth and shunt capacitance by means of Eq. 5, it may be found by aligning $B = 1$ mc and $C_i = 16 \mu\mu f$, giving $R_L = 10,000$ ohms as before.

Step 5: To ascertain whether $A = 50$ in Step 3 is a stable value of gain, a criterion of feedback through the tube grid-plate capacitance causing oscillation is determined. If the attenuation from plate to grid is set equal to the amplification from grid to plate as the critical value, then the desired gain must be less than the maximum usable gain. The value A_{max} is approximated by dividing R_L by the reactance of C_{OP} and thinking of this attenuation as a negative gain. This holds true when the input and output impedance are the

as in a multistage synchronous tuned i-f amplifier. The value of C_{GP} is determined by aligning $f_o = 30$ mc and C_{GP}

$= 0.0082 \mu\mu\text{f}$ and reading $X = 6.5 \times 10^5$ ohms. Now align this value of X and $R_L = 10,000$ and read the maximum usable gain

as 65 on the A_{max} scale. This value is greater than the desired gain of 50, so the amplifier is deemed to be stable.

Nomogram for designing single-tuned amplifier circuits like that shown. Numbered dashed lines indicate order of steps in designing an amplifier for desired stage gain and bandwidth and checking its stability

CHART FOR TE₁₁ MODE PISTON ATTENUATOR

Nomograph speeds finding attenuation constant for cylindrical waveguide operated in TE₁₁ mode below cutoff. May be used to design piston attenuators with minimum frequency dependence over given range

PISTON attenuators are useful because of their linear decibel scale and potentially high accuracy.¹ However, their attenuation constant is a slowly changing function of frequency due to the proximity of operating frequency to cutoff frequency and the frequency dependence of skin-depth.

The nomograph expedites determination of the attenuation constant, A , for the TE₁₁ mode in cylindrical waveguide. Effect of skin-depth is negligible for the TM₀₁ mode and nomographs

By CHARLES M. ALLRED

for this mode and the TE₁₁ mode for the case of infinite conductivity are available.²

The nomograph may be used to design attenuators having minimum frequency dependence over a given range and to determine that dependence after fabrication. In the latter case, consider radius $a = 2$ cm, conductivity $\sigma = 1.5 \times 10^7$ mhos per meter, and the frequency f

$= 1 \times 10^8$ cycles per second; then $a\sigma = 3 \times 10^5$ mhos, $af = 2 \times 10^4$ meters per second and extension to the A scale of a straight line through these points gives 15.94 db per radius for A . In attenuator design, choose values of a and σ to place the operating point at the right of the $a\sigma$ scale and about the knee of the af scale.

STAGGER-TUNED I-F DESIGN

Chart gives overall bandwidth for 3 db and any fractions of 3 db, for i-f amplifiers having 1 to 500 synchronous or stagger-tuned stages and up to 5 elements per stage

THE BANDWIDTH reduction factor R is here plotted as a function of the number of single or multituned stages n in the amplifier. The family parameter m represents the number of tuning elements in the interstage coupling network when all stages are synchronously tuned; thus, $n = 1$ for a simple RLC tuned interstage, and $m = 2$ for a double-tuned interstage. For a stagger-tuned amplifier, n is the number of n -uples and m is the number of elements in the general n -uple.

Example 1: Assume an amplifier is to have 8 stages using identical single-tuned interstage couplings. (a) For what 3-db bandwidth must each stage be designed if the overall bandwidth is to be 6 mc? (b) What will be the 0.5-db bandwidth?

Solution. (a) From the curves for $n = 8$ and $m = 1$, $R = 0.3$. Dividing overall bandwidth of 6 mc by this value of R gives 20 mc as the required bandwidth of each stage. (b) If n' stages cascaded give a certain 3-db bandwidth, each stage must be

By **MATTHEW T. LEBENBAUM**

down by $3/n'$ db and n of them will be down $(3/n') n = x$ db at that bandwidth. To determine the x -db bandwidth then, the R factor is determined for a number of stages n' where $n' = n (3/x)$; here n is the actual number of stages and $x < 3$ db. In the case at hand, $n' = 8 \times (3/0.5) = 48$, and $R = 0.12$ from the chart. The 0.5-db-down bandwidth then is 0.12×20 or 2.4 mc.

Example 2: An amplifier is to be built with an overall bandwidth of 20 mc and overall gain of 80 db; 6AK5 tubes are used with an assumed gain-bandwidth product ($g_m/2\pi C_T$) of 70 mc. (a) What is the minimum staggering required to achieve this result with 12 or less tubes? (b) If equally loaded double-tuned circuits were used (gain-bandwidth = $\sqrt{2} g_m/2\pi C_T$), how many stages would be required?

Solution. (a) Assume a value

of n , and determine R from the curve. This fixes the single-stage bandwidth required. From this, the gain per stage may be calculated from the gain-bandwidth product, and from this the overall gain. It will be found that it is impossible to achieve the desired gain with a synchronous single-tuned amplifier. Twelve stages arranged in six staggered pairs will not give the desired gain, either, but 9 stages arranged in triples or 8 in quadruples will. Possible systems are:

n/m	Tubes	db gain
6/2	12	75.5
3/3	9	80.5
4/3	12	102
2/4	8	80

(b) 12 double-tuned interstages give $R = 0.49$ ($n = 12$, $m = 2$). The overall gain then is 91.6 db for the desired bandwidth. This illustrates the superiority of multituned coupling over the corresponding order of staggering (91.6 db versus 75.5 db for the same number of staggered-pair tubes). Increasing the staggering to triples makes staggering still better, 102 db.

MICROWAVE DIFFRACTION CHARTS

The radius of the first Fresnel zone at various distances from the nearest terminal end of a microwave relay course can be determined from one nomogram. The adjusted distance required in Fresnel zone calculations is shown in the second alignment chart

By EARL D. HILBURN

MICROWAVE SIGNALS over line-of-sight courses are frequently observed to depart considerably from the free-space predictions.

Variations from free-space calculations are due to combinations of refraction and diffraction ef-

fects, as well as occasional absorption conditions due to rain, snow or fog. Of these factors, all but diffraction vary with weather conditions and combine to form the diurnal and seasonal variations noted in point-to-point relay services.

Although considerable information is available in the literature to enable the engineer to predict with fair accuracy the signal strength under given con-

ditions of temperature and percentage of water vapor in the atmosphere, the usual practice is to allow certain empirical margins of safety or fading factors based on long-term observations of relay signals at various frequencies. Diffraction effects, unlike those associated with refraction, do not change with time and weather conditions but are determined by the choice of operating sites and the intervening terrain. As the course line clearance is readily determined, and frequently is a factor under the engineer's control, diffraction factors are of practical interest in most microwave relay installations.

Fresnel Zone

From diffraction theory, when a wave strikes an intervening object a spherical wavefront radiates from the edge of the obstruction. The field intensity at any point beyond the obstruction is thus dependent upon the vector sum of the direct and scattered wavefronts reaching the receiver. A Fresnel zone may be defined as a circular zone about the direct path at such a radius that the distance from a point on this circle to the receiving point has a path length that is some multiple of a half wavelength longer than the direct path. Hence, according to Fresnel's zone theory, all the even-numbered zones will send wavefronts to the receiver in opposite phase to all those from odd-numbered zones.

The effective field intensity at the receiver will rise and fall above and below the free-space value as the scattered waves alternately reinforce and cancel

FIG. 1

FIG. 2

direct wave. The energy reaching the receiver from a Fresnel zone is proportional to the area of that zone and inversely proportional to the distance from the transmitter to the receiver. As the width of the Fresnel zones making up the zones decreases rapidly as the radius of the Fresnel circles increases, the first Fresnel zone is the only one of practical importance in diffraction studies of radio waves. It has been stated² that a good path for microwave transmission is one with full first-Fresnel-zone clearance. With an optimum path the signal strength at the receiver (excluding meteorological effects) is somewhat better than free space values due to the fact that the phase shift along a line from the transmitting antenna to the top of the obstruction and from the top of the obstruction to the second antenna is

about one-half wavelength greater than the phase shift of the direct path and some signal reinforcement is obtained.

Figure 1 indicates directly the radius of the first Fresnel zone as a function of distance and operating frequency. The construction shown assumes a plane wave (that the spherical wave has expanded to the point where the front is flat over the diameter of the diffraction zones).

The results given by this chart hold true only if the obstruction is very close to one end of the course. For accurate results at any point along the path, the setting on the distance scale should be adjusted in terms of the results given by Fig. 2. This enables the retardation on both parts of the circuit to be taken into account. Figure 2 is a simple reciprocal nomogram and, as

the scales are linear, they may be multiplied by different decimal factors as required.

For example, to find the clearance required for a good microwave path, assume an operating frequency of 7,000 mc, a total course length of 11.5 miles and a principal obstruction 3 miles from the transmitter.

A line connecting 3 and 8.5 on the outside scales of Fig. 2 gives an adjusted distance of 2.2 miles. Connecting this point with 7,000 mc on Fig. 1 shows a required clearance of 40 feet at the point in question.

In addition to determining easily the requirements for a good optical path, these alignment charts permit making quantitative studies of signal intensity conditions under various diffraction conditions including grazing or even badly obstructed courses where the receiver may be in a shadow area.

The principal course obstruction should be plotted showing the projected area normal to the direct course between stations. The Fresnel zones should be drawn in as circles about the dot representing the course path, the radii being obtained from the charts. (While the nomograms show only the first zone radius, values for higher-order zones may be obtained by multiplying the indicated value by the square root of the number of the zone being considered.)

Having drawn the zone areas, with respect to the masking obstruction, the net field intensity may be obtained by integrating the area of the exposed zones. This can be accomplished graphically by means of the Cornu spiral.³ In this manner, the departure from free-space values may be accurately estimated for any course.

COAXIAL-STUB FILTER

Undesired signals in a coaxial transmission line can be attenuated up to 30 db by connecting two stubs to the line, one for rejection and the other to correct the line impedance. Graphs give approximate stub lengths for any interfering frequency in range from 20 to 200 mc

By JAMES A. CRAIG

COAXIAL LINE stubs often can be effectively used in transmitter or receiver coaxial transmission lines to reduce or trap out specific spurious radiations or interfering signals. Stubs are well worth trying, since they are relatively inexpensive and can be depended upon to furnish up to 30-db additional attenuation to an undesired signal. Two stubs are used, one for rejection and one for correction, as shown in Fig. 1.

Receiver stubs are most easily fabricated from RG-58/U solid dielectric cable. Where stubs are to be used to suppress transmitter spurious radiations, a solid-dielectric cable should be used having the same power-handling capacity as is used between the transmitter and its antenna. The approximate length of the rejector stub for the undesired frequency can be determined from Fig. 2. A piece of

cable several inches longer than that called for should be connected into the transmission line as in Fig. 1, as close as practical to the transmitter or receiver. Use a pick or other sharp-pointed instrument to short-circuit the outer shield to the inner conductor at various points, starting from the outer end of the stub and working inward. Note at which point the short-circuit produces the greatest attenuation of the undesired signal and permanently short-circuit the cable there. Cut off the excess cable. This short-circuit may be best accomplished by collapsing the outer shield around the center conductor and soldering all around.

As Fig. 3 shows, the rejection

stub alone produces a certain amount of attenuation to the undesired signal. This is because it has been tuned to be a shorted half-wave section of line at the undesired frequency. As such, it presents close to zero impedance to this frequency at its point of connection to the main transmission line. However, at the desired frequency, the rejection stub will not be a shorted half-wave section of line and will therefore present either capacitive or inductive reactance to the line and thereby cause some degree of attenuation to the desired frequency. This effect can be overcome by adding a second stub called a correction stub, as shown in Fig. 1.

For various desired versus undesired frequency conditions, the length of the correction stub may vary from almost zero to one-half wavelength. The length of

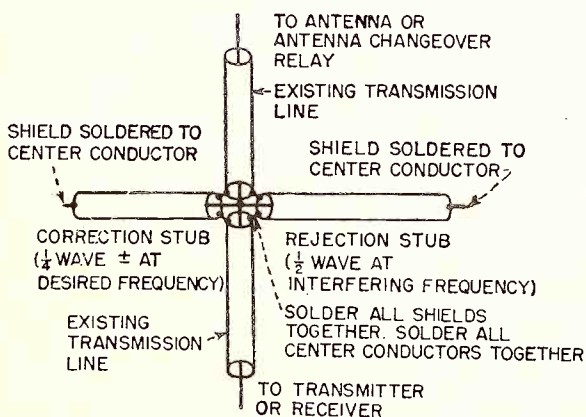

FIG. 1—Method of connecting stubs is same for both transmitting and receiving lines. Put stubs as close as possible to transmitter or receiver

FIG. 2—Correction and rejection stub lengths. Use left-hand scale in connection with Fig. 4 to determine correction stub length, since this is longer or shorter than a quarter-wavelength at some frequencies

FIG. 4—Curves showing line characteristics with stubs in place, as function of ratio of interfering signal to desired signal

Attenuation characteristics of stubs

quarter wave in solid dielectric cable is also plotted in Fig. 2 to show that the correction will be some value between a definite lower limit and a definite upper limit. In this case, the desired frequency should be used in determining the length of the correction stub. This stub is tuned permanently short-circuited as in the case of the rejection stub, except that the tuning is done to produce the least attenuation of the desired signal. If the correction stub were to be made exactly one-quarter wave long at the desired frequency, it would present infinite reactance (neither capacitive or inductive) to the desired signal. If being made shorter than a quarter wave it presents progressively less inductive reactance.

While being made somewhat longer than a quarter wave it presents progressively less capacitive reactance to the line. The amount of reactance in either case depends upon how much longer or shorter than a quarter wave the correction stub is made. This length is automatically arrived at in the tuning procedure given above.

Figure 4 shows whether the correction stub will be longer or shorter than the quarter-wave length shown in Fig. 2. To use Figure 4, determine what relation-

ship the interfering frequency bears to the desired frequency. As an example, if the desired frequency f is 40 mc and the interfering signal is 25 mc, the interfering frequency would be between $0.5f$ and $0.75f$. The lower curve shows that in this range the reactance presented to the line by the rejection stub is capacitive, and the upper curve shows that the correction stub should present inductive reactance and hence be shorter than a quarter wave, or shorter than the value called for on Fig. 2. The correction stub is thus utilized to balance out the reactance presented to the line by the rejection stub at the desired frequency.

Correction Stub Details

It is not necessary or desirable to show how many inches shorter or longer than a quarter wave the correction stub should be in chart form, since the precise length will be automatically arrived at as the stub is short-circuited in the tuning process. However, the upper curves in Fig. 4 do give the approximate length of the correction stub in terms of wavelength. In the example given above, these curves show that the corrector stub will be less than $\frac{1}{4}$ wave long. In this case, it is advisable to start with

a quarter-wave length of cable and short it at various points in the vicinity of an eighth wave to find the exact point.

Had Fig. 4 indicated the need for a capacitive correction stub (greater than a quarter wave and less than a half wave), it would be advisable to start with a half-wave length of cable and probe through the predicted point. Figure 4 is to be used chiefly as an aid in predicting the length of the correction stub and to help in visualizing the line conditions with the stubs in place.

A word of caution is advisable in a few specific cases. If the interfering frequency is approximately $\frac{1}{2}$, $\frac{1}{4}$ or $\frac{3}{4}$ of the desired frequency, stubs cannot be used. In these cases, the rejection stub will prove to be a full wavelength or multiple of a full wavelength at the desired frequency and will therefore present high attenuation to the desired frequency as well as to the interfering frequency. On the other hand, if the interfering frequency is exactly twice the desired frequency a correction stub will not be necessary since the one-half wave rejection stub will be an exact quarter wave at the desired frequency and will present infinite impedance to the desired frequency.

CHOOSING PENTODES FOR BROAD-BAND AMPLIFIERS

Gain-bandwidth products for pentodes are easy to calculate individually, but a graphic comparison of these broad-band amplifier-tube figures of merit yields a wealth of interesting and useful information. Such a comparison is shown in chart form below

THERE ARE MANY tubes now available for use in broad-band amplifiers. Pentodes are generally preferred to other types because of their relatively low grid-to-plate capacitance values. The chart below shows at a glance the relative suitability of 100 typical pentodes for use in broad-band amplifier circuits.

The important features of a pentode in this application are its transconductance or g_m , and the total capacitance to ground C , which is equal to the input plus the output capacitance. The plate resistance is much larger than the load resistance R and is usually neglected.

At normal frequencies the gain of the tube is $g_m R$. At high frequencies, if no compensation is used, the gain falls to 70 percent at the frequency where the re-

By JOHN R. WHYTE

actance of C is equal to R . If this frequency

$$f = \frac{1}{2\pi RC}$$

is taken as the bandwidth, then

$$\text{gain} \times \text{bandwidth} = \frac{g_m}{2\pi C}$$

and depends on the tube characteristics rather than on the external circuit. More complicated coupling networks will extend the bandwidth, but the gain-bandwidth product will still depend on the ratio of g_m to C .

Transconductance and total capacitance are used as coordinates. Different envelope styles are shown by different symbols. Using logarithmic scales, the contours of constant gain-band-

width product are lines sloping upwards at 45 degrees. The most desirable tube for this service is towards the lower right corner of the chart.

One use of this chart is to indicate tubes that are electrically similar, such as the 6AU6 and 6BH6.

The chart also shows that an improved tube can be obtained either by increasing the g_m , as shown by types 6AG5 and 6BC5, or by decreasing the capacitance, as shown by types 6AG5 and 6AK5.

Other similarities and differences are shown by tubes on the same diagonal line. For example, types 6AK5, 6CB6 and 6AH6 have the same gain-bandwidth product, with different values of transconductance and capacitance.

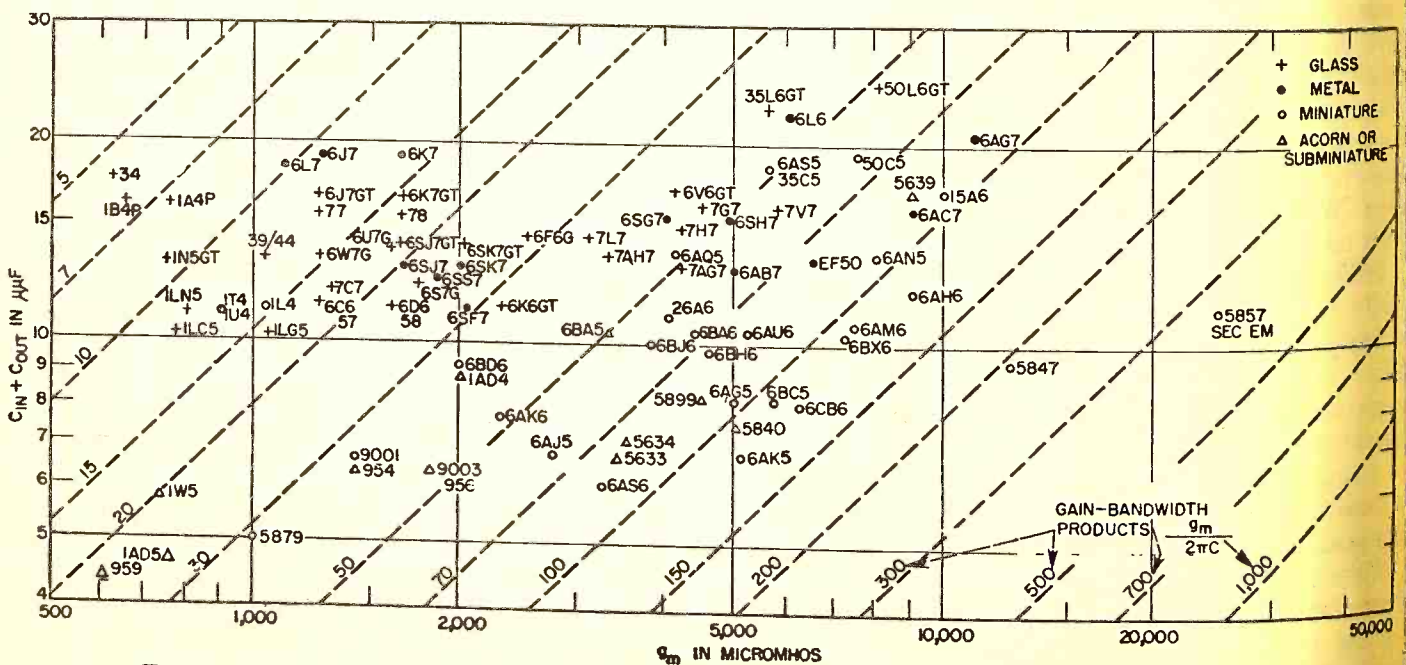

Chart enables designer to compare broad-band amplifier performance of various pentodes at a glance

SERIES-PEAKING NETWORK DESIGN

Nomograph permits rapid determination of series inductance and load resistance values for given cutoff frequency and shunt capacitance, and comparison of different circuit parameter combinations which give equal results

By JOSEPH F. SODARO

SERIES-INDUCTANCE peaking network compensation has the advantages over shunt peaking of greater amplification, smaller phase-angle error, and rapid attenuation beyond the cutoff frequency.

The basic series-compensated circuit is shown in Fig. 1. Each capacitance is a summation of the tube socket, wiring and associated tube interelectrode capacitance. The value of L is computed from

$$L = \frac{1}{8\pi^2 f^2 C'} \text{ henrys}$$

in which f is the cutoff frequency.

Fig. 1—Basic series-peaking network

The value of R is calculated from

$$R = \frac{1}{2\pi f C' \sqrt{2 \frac{C''}{C'}}} \text{ ohms}$$

If the ratio C''/C' is made equal to 2, the most satisfactory overall performance is obtained.¹ The Q of the series inductor should be 20 or more.

The nomograph is used by constructing a straight line from f

to the measured or calculated C' . The intersection of this line with the L scale shows the required inductance and provides a turning point from which a straight line is drawn to the measured or calculated C'' . The intersection of this line with the R scale shows the required load.

In the example $C' = 10 \mu\mu\text{f}$, $C'' = 20 \mu\mu\text{f}$ and $f = 4 \text{ mc}$. The series-peaking inductance L becomes 0.08 mh and R is 2,000 ohms.

TELEVISION I-F COIL DESIGN

Nomograph gives number of close-wound turns required to get desired inductance in range of values of interest to designers of coils for television, f-m and radar i-f transformers, eliminating considerable computational labor

By
JEAN HOWARD FELKER

THIS nomograph is based on a modification of H. A. Wheeler's inductance formula¹

$$L = \frac{r^2 n^2}{9r + 10l} \text{ microhenrys} \quad (1)$$

where r is the radius of the coil in inches, l its length in inches, and n the number of turns. In close-wound coils, l is a function of n . Substitution of nd , where d is the diameter of the wire in inches, for l in Eq. 1 gives an equation which can be solved for n to give

$$n = \frac{10dL + \sqrt{100d^2 L^2 + 36r^3 L}}{2r^2} \quad (2)$$

The complexity of Eq. 2 accounts for the unusual structure of the nomograph.

Dale Pollack² has shown verification for the formula $L = N^2 D / (102 S + 45)$ microhenrys, where D is the diameter of the coil in centimeters, N is the number of turns, and S is the ratio of the length of the coil to its diameter. Changing the centimeter dimensions of D to inches and employing Wheeler's symbols gives $L = r^2 n^2 / (8.85 r + 10l)$, verifying Eq. 1.

ELECTRONIC HEATING GRAPHS

Thermal power versus heating rate for materials of various specific heats. The two graphs are identical except that the one at the right is used for more accurate results with small quantities

Curves give power needed to attain desired temperature rise at given rate for materials having specific heats ranging from 0.04 to 1.0, when using either induction or dielectric heating. Separate curves cover evaporation of water

By A. P. BOCK

evaporation curve is a plot of $\text{kw} = 17.05 \text{ lb per min water evaporated}$.

Examples

Suppose it is desired to heat 50 pounds of steel per minute from 50 F to 1,350 F. Using a specific heat of 0.16, a value of 14 kw per 100-deg rise is obtained from graph A. Then for 1,300 deg rise, 13×14 or 182 kw of thermal power is required.

In another case, it may be desired to heat 10 lb per min (dry weight) of preforms, such as general-purpose molding compound, from 70 F to 270 F. Suppose this material contains

2-percent moisture, all of which will be evaporated by the time 270 F is reached. Using a specific heat of 0.35, a value of 6.1 kw per 100-deg rise is obtained from graph B. Then for 200-deg rise, 2×6.1 or 12.2 kw of thermal power is required to heat the dry material.

Two more factors of required power enter in owing to the moisture. In raising 0.2 lb of water per min from 70 F to 212 F or 142-deg rise, and using a specific heat of 1.0 for water, we have 0.35 kw per 100-deg rise or 0.5 kw for 142-deg rise. In evaporating 0.2 lb of water per min, the dashed-line curve of graph B indicates that 3.4 kw is needed. The sum of these products, then, totals 16.1 kw.

DESIGN OF R-F HEAT-TREATMENT

By **EUGENE MITTELMAN**

THE principal difficulty in the design of generators using the capacitive field method for r-f heat treatment is due to the characteristic potential distribution in the output circuit of such generators. The actual r-f potential across the object itself is a small fraction of the total high-frequency voltage across the electrodes. The potential distribution is a rather com-

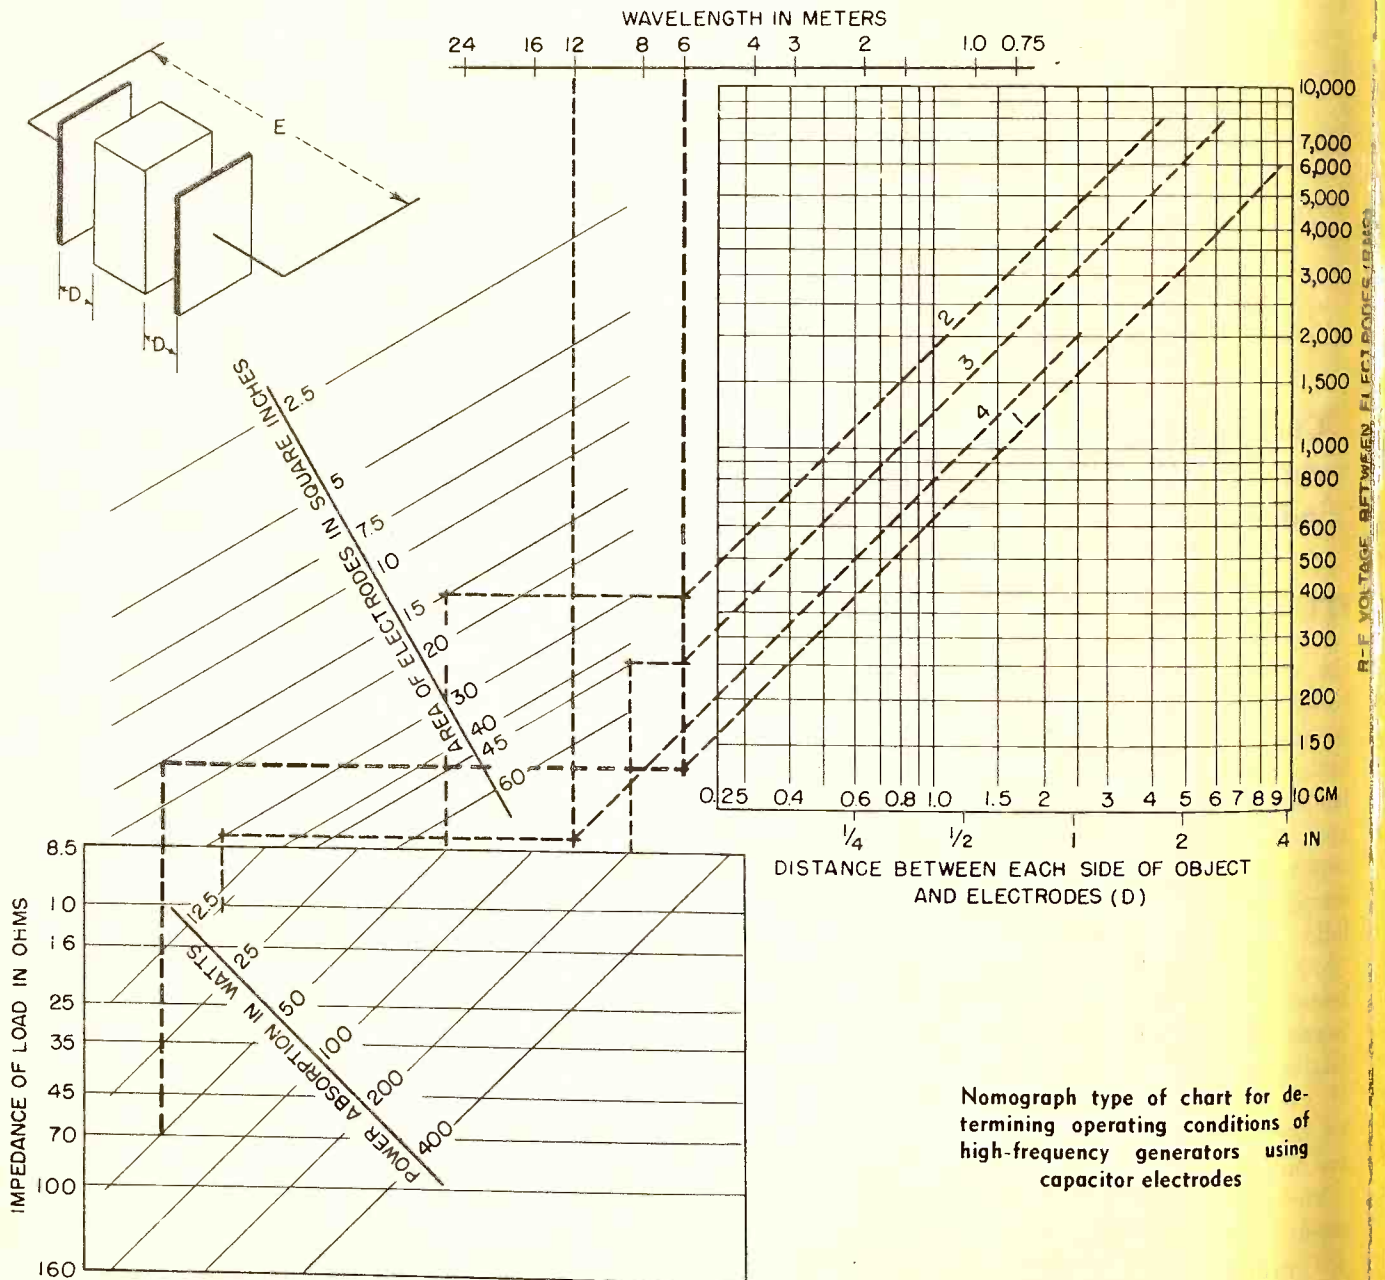

plicated function of a great number of variables including the wavelength, the capacitance between the electrodes and the object (which in turn is a function of the size of the electrodes, their distance from the object and the dielectric constant of the space between the electrodes), and the conductivity and dielectric constant of the object itself.

In general, both in the industrial and in the electromedical fields of application, the load impedance represented by the ob-

ject is small compared to the reactances of the coupling capacitances between object and electrodes, hence the necessity for an excessively high-frequency voltage across the electrodes for the achievement of certain required power absorption by the object.

Chart Design

The chart is designed to give the high-frequency voltage across the electrodes as a function of the distance D between

Nomograph type of chart for determining operating conditions of high-frequency generators using capacitor electrodes

Chart gives directly the effect of changes in electrode spacing and other operating parameters. Many heat-treatment generators using capacitive electrodes do not produce expected power output because of improper coupling to the load

ject and electrodes for any arbitrary values of the other variables as parameters. The chart may also be used to determine the power designated in the chart when the area of the electrodes and the load impedance are known. It shows up the limitations of the capacitor field method especially when large spacing is required. On the other hand it demonstrates that under favorable conditions considerable power absorption may be obtained even with relatively low voltages of the high-frequency field across the electrodes. Another fact is of special importance in the design of some all-purpose generators. At the maximum available frequency voltage in the circuit of an oscillator is not 0.9 the plate voltage or 1.8 times of the push-pull type generators, the chart will prove helpful in the proper choice of oscillator tubes.

Use of Chart

Select the lines of desired power absorption and load impedance at the lower left corner of the chart. From their intersection erect a vertical line and extend upward to the 30-square-inch line corresponding to the electrode area. From this intersection project horizontally to an intersection with a vertical line drawn through the wavelength on the wavelength scale. Through this last intersection point, a 45-degree line extending into the grid of logarithmic scales will give the potential as a function of the electrode spacing. For dielectrics between object and electrodes having constants greater

than unity, the readings on the horizontal scale, giving the distances between object and electrodes, must be divided by the dielectric constant.

Examples of Use of Chart

The correct use of the chart can be best explained by solving several examples.

(1) Given a generator with wavelength of 6 meters and a pair of electrodes 15 square inches in area, determine the voltage across the electrodes for a 70-ohm load to absorb 50 watts, provided the spacing between object and electrodes is one inch on both sides. From line 1 corresponding to this case we read off 1,600 volts rms. The voltages for other spacings may be taken from the same line.

(2) Given the same wavelength and the same geometrical conditions, a load impedance of 8.5 ohms, and a desired power absorption of 50 watts, find the r-f voltage across the electrodes. From line 2 we find the voltage must be increased to 3,700 volts rms.

(3) The power absorption can be increased greatly, even with less r-f voltage across the electrodes, if the area of the electrodes is increased. Line 3 corresponds to a 6-meter generator yielding 200 watts power absorption in a 8.5-ohm load between two electrodes whose area is 45 square inches.

(4) With a 12-meter generator the maximum available r-f voltage, with electrodes whose area is 30 square inches, shall be 2,000 volts rms. What power absorption can be expected if a load of 10 ohms equivalent im-

pedance is placed between the electrodes separated by 2.5-cm (1-inch) air spacing on each side of the electrodes? We find the answer by drawing a straight line at 45 degrees through the point corresponding to 2,000 volts and 2.5 cm (1 inch) on the graph (line 4) until it intersects the vertical 12-meter line. From here draw a horizontal to the 30-square-inch line and project down to the 10-ohm line. The power absorption will not exceed about 14 watts.

The physical arrangement of the chart is such that any of the variables can be taken as the independent factors merely by entering the chart at the right place. This feature is of particular advantage when the exact operating conditions are not known, and when several factors may be varied to obtain the desired power absorption.

Thus, for example, increasing the area of the electrodes increases the power absorption (all other factors remaining constant) in proportion to the increase in electrode area. Likewise, by halving the wavelength, the power absorption is doubled, if this is the only change in operation. Doubling the distance between electrodes and object means that the voltage must be doubled to maintain the same power absorption. Conversely, for a given impedance and power absorption, the voltage of the generator must be doubled if the spacing, D , is doubled.

As a result of many actual measurements on practical generators, it is found that the chart gives results in good agreement with practice.

NOMOGRAPH AIDS

FILTER DESIGNERS

Convenient nomograph aids design of power-supply filters. Percent ripple at output can be determined for various filters, including choke and capacitor input L-C filters and R-C types. Nomograph applies equally to full-wave and half-wave power supplies

By JOHN L. GLASER

PERCENTAGE RIPPLE for filters used with single-phase rectifiers operating from 60-cps sources can be easily and accurately determined with the accompanying nomograph.

Ripple factor is defined as the ratio of rms value of all a-c components of voltage to the d-c or average value of voltage. Generally, more than one frequency component is present in ripple, but a good approximation is obtained by considering only the lowest frequency component, especially when more than one filter section is employed.

The ripple factor of the voltage across the input of a capacitor-input filter is approximately

$$\frac{1}{\pi f R_L C_1}$$

where R_L is the d-c load resistance, C_1 the input capacitor and f the fundamental frequency.

On the chart, percentage ripple across the first capacitor is found by drawing a line connecting rectifier output voltage on scale *A* with rectifier output current on *B*. This line intersects *C* at the value of R_L . A line connecting R_L with the value of the input capacitor on *F* gives percentage ripple on *E*.

A second filter section consisting of a series inductance L_2 , followed by a shunt capacitance C_2 , reduces percentage ripple by the factor

$$\frac{1}{(2\pi f)^2 L_2 C_2 - 1}$$

where again f is the fundamental frequency of ripple. Within the range of L_2 and C_2 covered by the chart, $(2\pi f)^2 L_2 C_2$ is considerably greater than 1 so the ripple reduction factor is approximately

$$\frac{1}{(2\pi f)^2 L_2 C_2}$$

Ripple reduction factor of the second filter section is found on scale *I* by drawing a line connecting the value of L_2 on *J* with the value of C_2 on *H*. Ripple appearing across C_2 is obtained by multiplying the ripple across C_1 by the ripple reduction factor. This is accomplished by connecting these values on scales *E* and *I* with a straight line, giving the answer on *G*.

R-C Filters

The chart also provides for computation of ripple reduction resulting from a second filter section consisting of a series resistance followed by a shunt capacitance. In this case filter resistance is entered on *K* in place of the inductance which was entered on *J* as described above. The relation here states that the ripple reduction factor of the R-C filter is approximately

$$\frac{1}{2\pi f C_2 R}$$

Ripple across C_1 is multiplied by this factor.

These procedures apply to either half-wave or full-wave rectifiers using scale markings

labelled half-wave or full-wave. The two sets of markings account for different fundamental ripple frequencies.

Usually choke-input filters are designed so that the input choke has greater than critical inductance. Critical inductance is the minimum inductance that will provide uninterrupted current flow, and for 60-cps full-wave rectifiers, is equal to $R_L/1,132$. If the input choke has greater than critical inductance, the fundamental component of ripple at the rectifier output has an rms value 0.471 times the d-c component of rectifier output voltage. Thus percentage ripple at this point is approximately 47.1 percent.

Input choke L_1 and the shunt capacitor C_1 reduce this ripple by a factor $1/(2\pi f)^2 L_1 C_1$ giving the percentage ripple across C_1

$$\frac{47.1}{(2\pi f)^2 L_1 C_1}$$

This is found on the chart by drawing a line between L_1 on scale *D* and the C_1 on *F*. Percentage ripple across C_1 is found at the intersection of this line on *E*. Further ripple reduction resulting from an additional L-C or R-C section is found in the manner described for the capacitor-input filter.

Examples illustrating use of the chart are given in Fig. 1, 2 and 3.

These show analysis of performance of proposed filters with specific values of circuit components. Any component value could have been considered an

Basic filter design equations are combined in convenient form in this single nomograph

Solution for half-wave selenium rectifier supply using an R-C filter

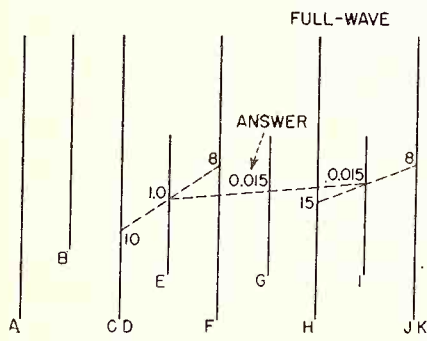

FIG. 2—Full-wave power supply using an L-C filter with capacitor input

FIG. 3—Solution for full-wave supply using a choke-input filter

own to be determined for defined filter performance. However, design procedure is usually to analyze various possible filter circuits made up of available components. The chart

provides a means for estimating the ripple for various filter circuits.

The chart is applicable only where power-line frequency is 60 cps. To predict the perform-

ance of a filter at some other frequency, f' , the values of capacitances and inductances should be multiplied by the factor $f'/60$ before entering these values on the chart.

SERVO POWER CALCULATIONS

Chart gives required shaft output power in watts for any combination of speed and torque of subfractional motors in tube-driven servo systems. Alternative slide rule method of finding power is also given

SERVO SYSTEM calculations must of necessity start with motor shaft output power to perform the specified work in a specified time. This involves the speed of shaft rotation and the torque required to perform the work. Since motors used in servo systems are usually sub-

By **OSCAR E. CARLSON**

fractional sizes, the horsepower unit is clumsy and awkward for expressing output power. Watts of output has become a common

means of expressing such power requirements.

The conversion of speed and torque requirements to a wattage equivalent is a simple arithmetical computation, but its very simplicity lends itself to even more simplified computation. The equations are

$$\text{Horsepower} = \frac{\text{rpm} \times \text{lb per in.}}{63,000}$$

$$\begin{aligned} \text{Watts} &= \frac{746 \times \text{rpm} \times \text{lb per in.}}{63,000} \\ &= \frac{\text{rpm} \times \text{lb per in.}}{84.4} \end{aligned}$$

This last equation may readily be laid out on a loglog chart so that the rpm x lb per in. factor may be translated into watts quite simply. The accompanying chart does this.

As with most loglog coordinate charts, a slide rule may be utilized for these calculations without using the slider. Set the righthand 1 of the B scale under 8.44 in the righthand log cycle of the A scale, as shown below the chart. With the A scale now representing rpm x lb per inch from 10 to 1,000, the wattage may be read directly under that product on the B scale, with that scale reading from 0.1 to 10 watts. A multiplier of 10 or 100 may of course be used to make calculations up to 1,000 watts, if so required.

R-F COUPLING NOMOGRAPH

Gives coefficient of inductive coupling of an r-f transformer directly from Q-meter measurements. Procedure permits correcting for effects of distributed capacitance

By **RAYMOND E. LAFFERTY**

WHEN MEASURING the coefficient of inductive coupling of an r-f transformer with Q-meter, one winding of the transformer is connected to the inductor terminals of the Q-meter and the capacitance of the Q-meter circuit is tuned to resonance with the second winding open to give C_1 , and shorted to give C_2 . Then

$$k = \sqrt{1 - (C_1/C_2)} \quad (1)$$

Equation 1 also neglects the effect of distributed capacitance in either or both windings, and

is valid only if the Q's of both windings are greater than 10. Where primary distributed capacitance C_p and secondary distributed capacitance C_s are both present to a significant degree,

$$k = \sqrt{1 - U} \quad (2)$$

$$\text{where } U = \frac{1}{(1 - \gamma^2) \left(\frac{C_2 + C_p}{C_1 + C_p} \right) + \gamma^2}$$

$$\begin{aligned} \gamma^2 &= (f/f_0)^2 \\ f &= \text{Q meter frequency} \\ f_0 &= \text{self-resonant frequency of secondary, or } 1/2\pi \sqrt{L_s C_s} \end{aligned}$$

Where C_p is significant and C_s is negligible ($\gamma^2 \cong 0$);

$$k = \sqrt{1 - V} \quad (3)$$

where $V = (C_1 + C_p)/(C_2 + C_p)$

Where C_s is significant and C_p is negligible ($C_p < 5$ percent of C_1);

$$k = \sqrt{1 - W} \quad (4)$$

$$\text{where } W = \frac{1}{(1 - \gamma^2) \frac{C_2}{C_1} + \gamma^2}$$

The nomograph is used by extending a straight-edge from C_1/C_2 , tangent to the correct γ^2 curve, and reading its intersection with the scale for k . If C_s is small enough to be neglected, γ^2 is approximately zero and the zero curve should be used.

If both windings of the transformer have appreciable capacitance, C_p and f_0 should be measured before the coils are inductively coupled.

Example 1. The Q-meter tunes to 460 kc with 210 $\mu\mu\text{f}$ of capacitance when one winding of an r-f transformer is connected to the inductor terminals and the other winding is left open. When the second winding is shorted the Q-meter capacitor must be increased to 375 $\mu\mu\text{f}$ to maintain resonance at 460 kc. The self-resonant frequency of the secondary is found to be 840 kc, and C_p can be considered negligible. From this, $C_1/C_2 = 0.56$ and $\gamma^2 = 0.3$. Using the nomograph, k is 0.6.

Example 2. $C_1 = 95 \mu\mu\text{f}$, $C_2 = 116 \mu\mu\text{f}$, $C_p = 15 \mu\mu\text{f}$ and C_s is negligible (hence $\gamma^2 \cong 0$). From these data, $(C_1 + C_p)/(C_2 + C_p) = 0.84$ and the nomograph shows k to be 0.4.

VECTOR COMPUTATIONS

Aids in transforming rectangular to polar coordinates, and for determining the reciprocal of a complex number. Number of operations involved is much less than with alternative sliderule methods, particularly when working with multimesh networks. Range of charts is easily extended

By PAUL W. KLIPSCH

THE practical use of complex quantities in electrical engineering is almost as old as the profession itself. The charts presented here aid in performing two important vector operations, Fig. 1 transforming an equation in rectangular coordinates, $z = x + jy$, to its polar form, a / θ , and vice versa. Figure 2 is useful in determining the reciprocal of a complex number, that is in solving the equation

$$x + jy = (a + jb)^{-1}$$

Of course the sliderule can be used in solving these problems, but the number of operations can become rather numerous.

Getting the Vector Sum

Consider the problem of finding z in the equation

$$x + jy = z$$

The absolute value of z (written $|z|$) is readily found in two operations on a sliderule as follows: On the C and D scales take the ratio of x and y such that the ratio, greater than unity, appears on the D scale at the index mark on the slide. Opposite this

ratio find its square on the A scale, add one, run the slide up to this new point, and under x or y , whichever is the smaller, on the C scale will be found $|z|$ on the D scale. For example, take $3 + j4$. Set 3 on the C scale opposite 4 on the D scale which places the slide index at 1.333 on the D scale and 1.778 on the A scale. Add 1 and run the slide index up to 2.778 on the A scale. Under 3 on the C scale find the answer, 5, on the D scale. This is in effect a solution of the equation

$$|z| = (x^2 + y^2)^{1/2} = y [(x/y)^2 + 1]^{1/2}$$

FIG. 1—Graph for converting a complex number from rectangular to polar coordinates and vice versa. The x and y axes are spaced logarithmically; the curved lines represent the argument a ; the straight lines from lower left to upper right give the phase angle, b

Adding the phase angle involves the additional operation of determining the value of the phase angle, $\angle z = \tan^{-1}y/x$.

Chart for Vector Sum

An alternate of the sliderule method is the use of the chart of Fig. 2 in which a transformation from rectangular to polar coordinates is performed in a single operation. The modulus and argument (absolute value and angle) can be found from the x and y components or the reverse operation can be performed. For example, locating the point (3, 4) on the rectangular system gives $|z| = 5$ on the polar coordinates and $\angle z = 53^\circ$ on the diagonal coordinates. A series of operations in a multimesh network, with a multiplicity of sliderule steps

become tedious, but the chart of Fig. 2 gives each reciprocal in a single operation. The vector reciprocal is the solution of the equation

$$x + jy = (a + jb)^{-1}$$

and the solution by means of the chart is simply that of looking up the numbers a and b on the rectangular system and then finding the coordinates of the same point (a, b) on the curvilinear system which are x and y , the sign of y being reversed with respect to the sign of b .

Extending the Range

When the ratio of a to b lies outside the range 1/10 to 10 a simple approximation may be used, and when the numbers are otherwise off the chart a factor of ten or power of ten may be

applied to the number to arrive at a value locatable on the chart, looking up the converted value on the chart and applying the same factor to the answer. To use the $3 + j4$ example again, the reciprocal is found to be $0.12 - j0.16$. As an example of a complex number outside the scale of the chart, take $30 + j40$. Using a factor 1/10, $(30 + j40)/10 = 3 + j4$ and the reciprocal is $(1/10) \times (0.12 - j0.16) = 0.012 - j0.016$. For the case in which the ratio of a and b is greater than 10, the chart is not needed to arrive at a close approximation. For example, let $a + jb = 3 + j40$. The reciprocal is $3/40^2 - j1/40 = 3/1600 - j1/40 = 0.001875 - j0.025$ within less than 1 percent, the true value being close to $0.00187 - j0.0249$.

FIG. 2—For determining the reciprocal of a complex number. As an example, the reciprocal of $z = a + jb = 3 + j4$ on the a and b scales (top and right) is found to be $z^{-1} = x - jy = 0.12 - j0.16$ on the x and y scales (bottom and left)

SQUARE ROOT of a COMPLEX NUMBER

Tedious and time-consuming calculations required in finding the square root of a complex number in transmission line and filter calculations can be greatly simplified through the use of this graph

By ROBERT G. NISLE

IN designing certain types of electrical networks the need frequently arises for evaluating the square root of a complex number such as an impedance. If the impedance is expressed in polar coordinates any root can be quickly and easily found, but if the expression is originally given in rectangular coordinates, the required operations are tedious and time consuming. The impedance must first be converted from rectangular to polar form, the square root is then determined, and finally the result is reconverted into rectangular coordinates, thereby requiring three separate and distinct operations.

A method by which the square root of any complex number, expressed in rectangular coordinates, can be easily and quickly determined, also in rectangular coordinates, is given here. The errors to be expected are simply those which result from reading any graph and are negligible for most engineering purposes.

To Extend the Range

If it is necessary to consider ranges outside that covered by the graph, this can be done by multiplying the original complex number by some suitable scale factor (such as 0.01 or 100) so that the problem may be fitted into the range for which the

chart is drawn. The final result will then have to be multiplied by the reciprocal of this scale factor (for example, 100 or 0.01, respectively).

If the original complex number is

$$Z = a + jb$$

the problem before us is to determine

$$Z^{\frac{1}{2}} = x + jy$$

The double set of coordinates relate the quantities x , y , b , and $K = a/b$ so that when any two are known, their intersection determines a position or point on the chart from which the remaining two quantities may be determined. To use the chart, first determine $K = a/b$. Then, knowing K and b , find the intersection of these two coordinates on the vertical and horizontal axes. The point of intersection thus found will also be the point of intersection for the desired values of x and y , read off from the slanting scale.

It should be noted that $Z^{\frac{1}{2}}$ has two roots, a positive root and a negative root. Geometrically, these two possibilities are indicated in graphical form by means of vectors which are directed in opposite directions, or are 180 deg apart. The physical requirements of the problem must be considered when deciding which of the two roots is to be used.

Example 1: Assume that we

have an impedance

$$Z = a + jb = 15 + j20$$

and that it is required to determine

$$Z^{\frac{1}{2}} = x + jy$$

First determine $K = a/b = 0.75$. Locate the intersection of the coordinates, $K = 0.75$ and $b = 20$. At this point read $x = 4.46$ and $y = 2.25$. The desired result is then

$$Z^{\frac{1}{2}} = x + jy = 4.46 + j2.25$$

or its negative value,

$$Z^{\frac{1}{2}} = -x - jy = -4.46 - j2.25$$

Example 2: If the complex number is

$$Z = -15 + j20$$

the result is

$$Z^{\frac{1}{2}} = x + jy = 2.25 + j4.46$$

or, alternatively

$$Z^{\frac{1}{2}} = -x - jy = -2.25 - j4.46$$

Example 3: If the impedance is

$$Z = -15 - j20$$

the final result is

$$Z^{\frac{1}{2}} = -2.25 + j4.46$$

or

$$Z^{\frac{1}{2}} = 2.25 - j4.46$$

Example 4: If the impedance is

$$Z = 15 - j20$$

the final result is

$$Z^{\frac{1}{2}} = -4.46 + j2.25$$

or

$$Z^{\frac{1}{2}} = 4.46 - j2.25$$

Example 5: If the impedance is

$$Z = 150 + j200$$

we find that $K = 0.75$, $b = 200$, $x = 14.2$ and $y = 7.1$. The result is

$$Z^{\frac{1}{2}} = 14.2 + j7.1$$

R-F POWER-AMPLIFIER DESIGN CHART

By E. H. SCHULZ

THE method described here is based on the following assumptions:

1. The I_p - E_p curves are parallel and equidistant for equal grid bias increments in the positive grid region.
2. $I_p = k(e_g + e_p/\mu)$.
3. The amplification factor, μ , is a constant.

In addition, the grid current and the peak plate current must be approximated.

Symbols are as follows:

- I_m = peak plate current.
- I_1 = peak value of fundamental component of plate current.
- I_2 = peak value of second harmonic component of plate current.
- I_{d-c} = d-c plate current.
- E_b = plate supply voltage.
- E_c = grid bias voltage.
- E_i = peak input from driver stage.
- E_o = peak output voltage.
- $E_{p\min}$ = minimum value of plate voltage.
- $E_{g\max}$ = maximum positive value of grid voltage.
- P_i = d-c plate input power.
- P_o = r-f power output.
- θ = angle of conduction in degrees of fundamental frequency.

If provision is made to vary the principal parts of the circuit (such as grid bias, driving voltage and load coupling) by a small amount, optimum operating conditions may be obtained. Although the method is outlined for class-C design, it may be used for class-B design by making the angle of conduction equal to or slightly larger than 180 degrees.

Since the allowable peak plate current is not given by the tube manufacturer, it must be approximated by multiplying the emission as given in Table I by the filament heating power in watts. Allowance should be made for grid current (usually 10 to 20 percent). For tetrodes and pentodes, allowance should be made for screen current.

Table I — Maximum Emission Current for Various Filament Materials, to be Used in Choosing I_m

Type of filament	Maximum Emission ma per watt of heating power
Tungsten ¹	2 to 4
Thoriated Tungsten ²	10 to 35
Oxide Coated ³	10 to 40

¹ Based on safety factor of 1. Multiply by 0.6 to 0.7 for linear amplifier or for modulated stage to insure linearity.
² Based on safety factor of 3 to 10.
³ Based on safety factor of 5 to 15.

Table II — Comparison of Design and Experimental Values for Class C Amplifier Using Type 10 Tube

	Design	Experimental
I_{d-c}	60	62.5
P_o	19.6	18.8
P_i	30	31.2
$E_{g\max}$	110	118
$E_{p\min}$	130	123
I_g	10-12	12

$E_b = 500$ Volts $f = 800$ kc
 $\theta = 135^\circ$, $E_c = 138$, $I_m = 282$, $I_1 = 106$

Case I. Class C Amplifier with Given Plate Input Power

1. Select tube and plate supply voltage, E_b (high values give greater efficiency but require greater driving power).
2. Determine the d-c plate current, $I_{d-c} = P_i/E_b$.
3. Select several angles of conduction between 100 deg and 130 deg (small angles give greater plate efficiency but require greater driving power). Determine the peak plate current, I_m , and the fundamental component, I_1 , from I_{d-c} and the

chart for each angle.

4. Check I_m against allowable value.

5. Consult I_p - E_p curves and select values of $E_{g\max}$ and $E_{p\min}$ to give required I_m . $E_{p\min}$ should be as small as possible for maximum efficiency, and $E_{g\max}$ should be less than 80 percent of $E_{p\min}$ for low driving power. In the case of tetrodes and pentodes $E_{g\max}$ should not exceed 80 percent of the screen voltage nor should $E_{p\min}$ be less than the screen voltage.

Since the manufacturer's I_p - E_p curves do not extend far enough into the positive grid region, some I_p - E_p curves for positive grid voltages must be sketched in by assuming that the curves for constant grid voltage increments are equidistant and parallel to the straight-line portion of the zero grid voltage curve.

6. Calculate the grid bias from

$$E_c = E_b/\mu + \frac{(E_{g\max} + E_{p\min}/\mu)\alpha}{\cos(\theta/2)}$$

where $\alpha = \frac{1 - \cos(\theta/2)}{(1 - \cos(\theta/2))}$ may be taken directly from the chart.

7. Calculate peak value of the driving voltage $E_i = E_c + E_{g\max}$.

8. Calculate power output, $P_o = I_1 E_o / 2$ where $E_o = E_b - E_{p\min}$. Also calculate plate dissipation $= P_i - P_o$.

9. Assuming that the grid current is 10 to 20 percent of the plate current, determine the approximate driving power from E_i multiplied by the d-c grid current.

10. Check I_{d-c} , E_b , driving power, and plate dissipation against maximum allowable for tube.

11. Choose the angle of conduction that gives the most desirable operation from the standpoint of output, efficiency and

Approximate method of designing class-B and class-C amplifiers, giving sufficient accuracy for most engineering work. Accuracy obtainable for various operating parameters is better than 10 percent for example chosen

avg power. If desired, this may be repeated for several values of E_{pmin} and E_{gmax} .

2 Design tank circuit:
Equivalent impedance of tank,
 $Z_o = E_o / I_1$,

$Z_o = 2\pi f Q$ henrys.
 $C = 1 / (2\pi f)^2 L$ microfarads.

θ may be set arbitrarily between 10 and 15 or may be established by the allowable 2nd harmonic as follows:

$$\text{percent 2nd harmonic} = \frac{66}{I_1} \times I_2$$

$I_2 =$ second harmonic component of plate current for θ . A large Q will give a large harmonic component but will increase the heating loss in the tank circuit.

Class C Amplifier with Given Power Output

Select tube and E_b as in case I.

Choose allowable I_m from case I.

Select E_{pmin} and E_{gmax} as in case I.

Calculate $E_o = E_b - E_{pmin}$
 $P_o = 2P_o / E_o$.

From the ratio I_1 / I_m determine θ and I_{d-c} .

Calculate plate input $P_i =$
and plate dissipation $=$

Calculate E_c , E_t , and driver power as in steps 6, 7, and 10.

Repeat for several values of θ and try different combinations of E_{pmin} and E_{gmax} for a given I_m .

Better results from the point of efficiency, tube life giving power.

Design tank circuit as in case I.

Repeat for several values of θ and try different combinations of E_{pmin} and E_{gmax} for a given I_m .

Better results from the point of efficiency, tube life giving power.

Design tank circuit as in case I.

Repeat for several values of θ and try different combinations of E_{pmin} and E_{gmax} for a given I_m .

Better results from the point of efficiency, tube life giving power.

Chart giving approximate operating parameters for optimum operating conditions of class-B and class-C r-f power amplifiers

be adjusted so that the correct E_{gmax} is obtained, as measured by a peak voltmeter. The coupling of the load to the tank circuit should then be increased until the desired plate current is obtained. The tank circuit should be retuned each time that the coupling is changed. Small vari-

ations from the calculated values may improve the overall operating conditions. In amplifiers using tetrodes and pentodes the tank should be tuned for maximum output rather than for minimum plate current, because the plate current is not very critical with respect to tuning.

ATMOSPHERIC ABSORPTION CHART

Varying absorption of microwaves, millimeter waves and infrared rays by the atmosphere is analyzed and charted for region from 0.001 mm to 10 cm. Absorption peaks should be avoided when designing radar and communication equipment

By **ARNOLD SHOSTAK**

FACTORS affecting the amount of absorption experienced by a propagated electromagnetic wave include: path length, water vapor content and oxygen content of the air. The combined effects of these factors are shown in the accompanying chart.

The drop in 4-cm waves is about 0.01 db per kilometer, whereas in the oxygen absorption band around 5 mm the drop may be as high as 10 db per km. The infrared waves from 1 to 500 microns (0.001 to 0.5 mm) usually sustain complete absorption in the first 15 meters, with ensuing attenuation due to scattering.

Water exists in the atmos-

phere both in the form of rain drops and in the form of vapor. The amount of water per unit volume is dependent on temperature. Rain drops, as a function of their diameter and the wavelength of the propagated wave, mostly result in scattering of the wave energy. Water vapor, on the other hand, is made up of H₂O molecules which have a permanent electric dipole moment. This moment interacts with the electric vector of the impinging electromagnetic field, with resultant energy absorption. The water vapor absorption band in the region of 1.33 cm is due to this type of interaction. Carbon dioxide also has

a permanent electric dipole moment that causes absorption.

Oxygen does not have a permanent electric dipole moment; it does, however, possess a permanent magnetic moment. This moment interacts with the magnetic vector of the electromagnetic wave to cause absorption, principally around 5 mm.

Most of the factors governing absorption of electromagnetic waves are thus manifested in the very short wavelength regions, from 0.001 mm to about 20 mm. Waves above 3 cm are attenuated by scattering, especially in rainstorms, but the relative effect is usually small compared to absorption in the smaller wavelength regions. In the infrared, violent oscillations in the plot of wavelength versus absorption are noted, principally due to the closely-spaced energy levels of the various molecules of the gases making up the atmosphere. Infrared transmission at sea-level is limited to very short ranges and must exploit the wavelengths of low absorption indicated in the chart. As may be noted, these bands of low absorption, called windows, are of very narrow width, compelling the use of very selective generators and receivers for successful transmission of electromagnetic energy over significant distances at these wavelengths.

Relative atmospheric absorption at sea level and temperature of 20 deg C

HIGH Q MEASUREMENT

Decay of oscillations in pulsed resonant circuit is measured oscillographically, and result is applied to nomograph to obtain Q directly. Technique has been applied to measure values of Q of resonant circuits at frequencies as high as 15 mc

HIGH VALUES of Q (in excess of 1,000) cannot easily be determined under steady-state conditions, however, the transient characteristics of a resonant circuit suggest a method. When a series resonant circuit is excited by a unit impulse, a train of damped oscillations is generated, as indicated by the waveform shown on the accompanying nomograph. The amplitude of the envelope of this waveform at time t_1 may be expressed

$$A_1 = A_0 e^{-\frac{R t_1}{2L}} \quad (1)$$

where A_1 = the amplitude of the envelope at time t_1 , A_0 = the amplitude of the envelope immediately following excitation, R = total equivalent series resistance of the circuit, and L = the equivalent series inductance of the circuit.

The Q of a shock-excited series circuit may be expressed by

$$Q = \frac{2\pi f_0 L}{R} \quad (2)$$

where f_0 is the natural series resonant frequency. Combining Eqs. 1 and 2 and choosing an excitation pulse repetition frequency such that

$$prf = 1/t_1$$

$$Q = \left(-\frac{\pi}{\ln(A_1/A_0)} \right) \left(\frac{f_0}{prf} \right) \quad (3)$$

The accompanying nomograph solves this equation.

Sample Measurement

The laboratory equipments required to obtain the necessary data are a signal generator to provide the prf, a pulse generator, and an oscilloscope to measure the train of damped oscillations.

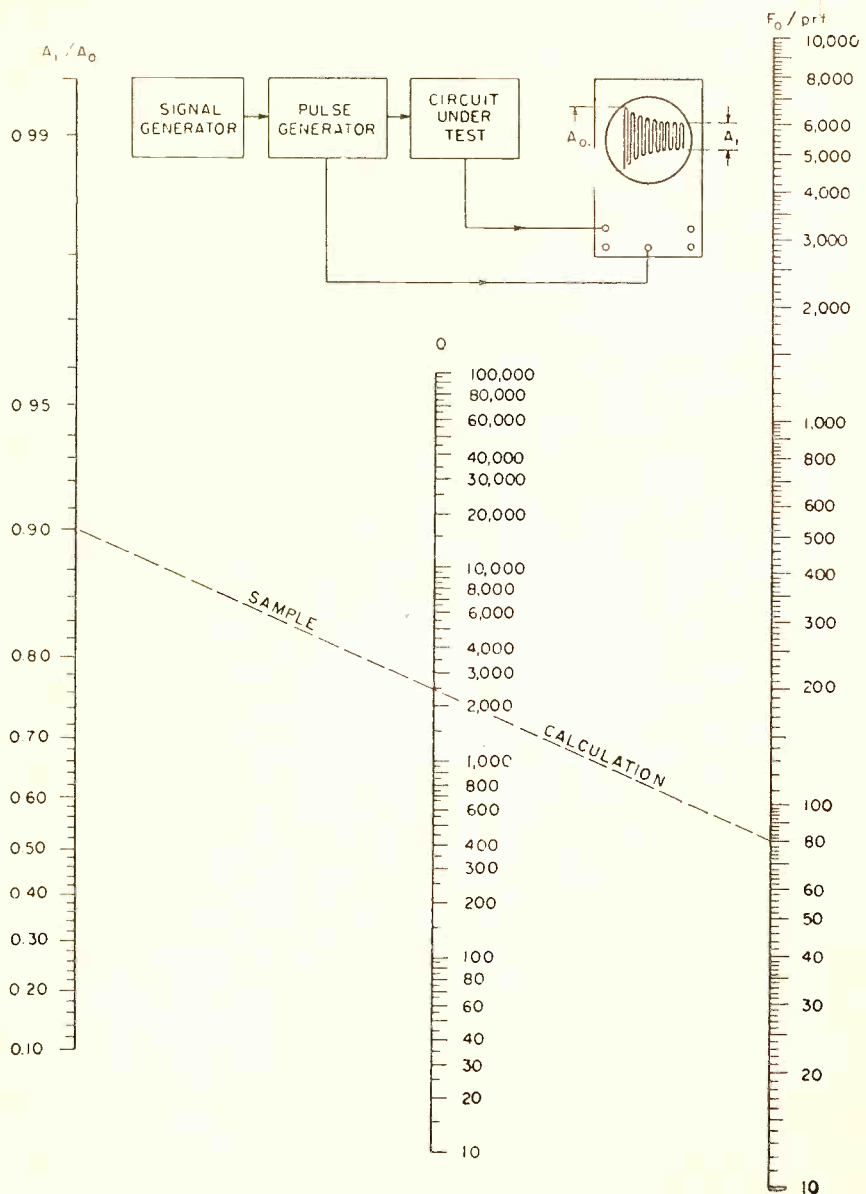

By WILLIAM J. SPAVEN

The equipment is arranged so that the signal generator drives the pulse generator at the required prf. The pulse generator drives the circuit under test, and the oscilloscope reads the output of the circuit, as shown in the

block diagram on the nomograph.

A high-Q circuit, resonant at 20 kc, was to be tested. The ratio A_1/A_0 was determined from the oscilloscope pattern to be 0.90. The prf was 250 cps, or $f_0/prf = 80$. A straight line drawn from $A_1/A_0 = 0.90$ to $f_0/prf = 80$ intersects the Q line at $Q = 2,500$. Verifying with Eq. 3,

$$Q = \left(-\frac{\pi}{\ln 0.90} \right) (80) = 2,420$$

UNIVERSAL EQUALIZER CHART

Modification of familiar Smith chart consolidates on one time-saving plot all positive-value solutions to the two general equations for series, shunt and bridged-T audio equalizers

THE single chart in Fig. 1 replaces as many as eleven conventional equalizer charts, yet gives all solutions containing positive resistances or conductances for the commonly used equalizer structures of Fig. 2. The chart is derived by applying to the two general forms of equalizer equations (Eq. 10 and

By **D. A. ALSBERG**

11 in Fig. 2) the bilinear transform

$$u + jv = (1 + \zeta)/(1 - \zeta) \quad (12)$$

where ζ is a complex number. This transforms the conventional rectangular grid of u and v

to a set of orthogonal circles, all of which pass through the point $\zeta = +1$, and the circle $u = 0$ is identical with the unit circle in the ζ plane. This grid of orthogonal circles representing the u and v coordinates is identical to the grid of the familiar Smith chart.

IMPEDANCE OR
ADMITTANCE
COORDINATES

$\alpha = \text{DB}$
 $\beta = \text{DEGREE}$
 $u = R/R_0 \text{ OR } G/G_0$
 $v = X/R_0 \text{ OR } B/B_0$

FIG. 1—Universal equalizer chart

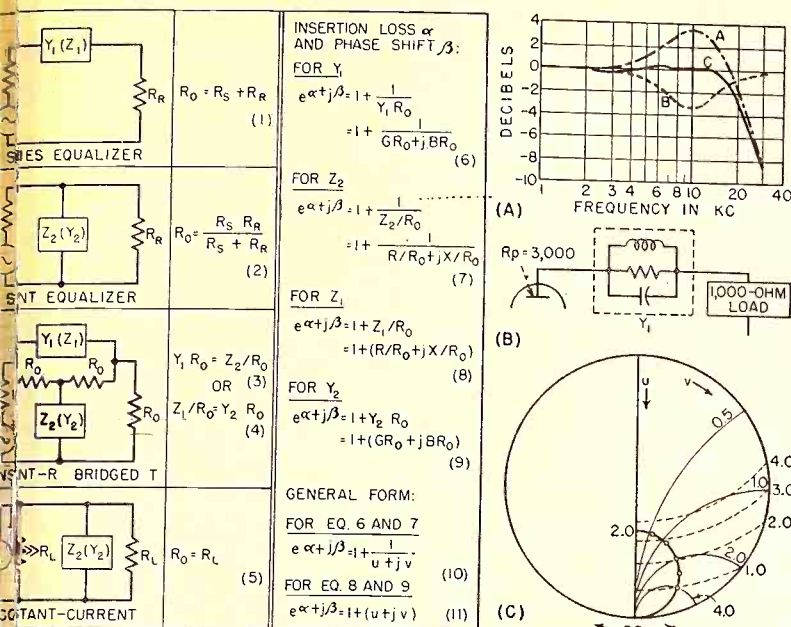

FIG. 2—Basic equalizer circuits, pertinent equations, and example

Using Eq. 10 in the ζ plane, lines of constant insertion loss become circles centered on the point $\zeta = -1$ and whose loci are defined by

$$|b| = -20 \log |(1 + \zeta)/2| \quad (13)$$

Lines of constant phase shift pass through the point $\zeta = -1$ whose angle from the real axis in the ζ plane is equal to the phase shift.

The solution of Eq. 11 in the ζ plane is essentially the same as above except that the center for the loss circles and phase shift is now the point $\zeta = +1$ and the loci of the loss circles are defined by

$$|b| = -20 \log |(1 - \zeta)/2| \quad (14)$$

Applications

Series and shunt equalizer circuits are useful when it is necessary to maintain constant impedance, such as in electron tube interstages. When the load must have constant impedance, the bridged-T equalizer is used. The constant-current equalizer is a special case of the shunt equalizer and is particularly useful in electron tube circuits which behave substantially like constant-current generators, such as pentodes. One use is to compute the effect of shunting parasitic ca-

pacitances on the gain and phase of an electron tube stage. In this case the parasitic shunt reactance would be considered Z_s .

While Eq. 1 to 9 have been written for a pure resistance R_o , R_o may be replaced in all these expressions by a complex impedance Z_o . Then the values u and v in the chart represent the real and imaginary components of the fraction Z/Z_o or the product YZ_o . The chart is also useful when measuring impedance using the insertion loss and phase principle.

Example of Use

Curve A in Fig. 2A represents an amplifier response curve. The objective is to flatten the response peak at 10 kc. A convenient place to perform the equalization is found in the plate circuit of a tube which has an internal plate resistance $R_p = 3,000$ ohms and works into a load of $R_r = 1,000$ ohms, as in Fig. 2B. The shape of curve A suggests use of a parallel-tuned circuit shunted by a resistance in the case of a series equalizer. With three independent elements in the equalizer, three independent parameters may be chosen. As first parameter we choose to tune the circuit to ω_o

= 10 kc. As second parameter we choose to make the equalizer loss exactly 3.5 db at 10 kc, and as third parameter we decide to match exactly the excess gain of 1 db at $\omega_1 = 5$ kc.

Proceeding with the computation on a normalized admittance basis, at resonance the susceptance of the equalizer must be zero. Entering the chart as shown in Fig. 2C on the zero-susceptance line, we find the 3.5-db loss circle intercept at the 2.0 conductance circle. Thus the equalizer must contain a normalized conductance of $GR_o = 2.0$.

At 5 kc the loss was set to 1 db. We now find the intercept between the 2.0 conductance circle and the 1.0-db loss circle at a susceptance of 4.0. From resonance at ω_o

$$\omega_o CR_o - \frac{1}{\omega_o L/R_o} = 0 \quad (15)$$

From the solution of Eq. 10 at ω_1

$$\omega_1 CR_o - \frac{1}{\omega_1 L/R_o} = 4.0 \quad (16)$$

then

$$CR_o = \frac{4}{\left(\omega_1 - \frac{\omega_o^2}{\omega_1}\right)} = 4.25 \times 10^{-6} \quad (17)$$

$$L/R_o = 5.97 \times 10^{-6} \quad (18)$$

From Eq. 17 and 18 the net normalized susceptance of the network at any frequency may be determined. To find the loss associated with each of these susceptance values the equalizer chart is entered on the 2.0 conductance circle and the intercept with the computed susceptance circle is located, at which point the loss value is read. The result is plotted in curve B on Fig. 2A, and the resulting net transmission characteristic is plotted as curve C.

Assuming curve C to be adequately flat, the actual element values of the equalizer are found: From Eq. 1, R_o is 4,000 ohms. Substituting this in $GR_o = 2.0$ gives 2,000 ohms for $1/G$. From Eq. 17, C is 0.0106 μ f. From Eq. 18, L is 23.9 mh.

REVERBERATION TIME NOMOGRAPHS

By R. C. COILE

REVERBERATION TIME is the length of time required for the intensity of a sound to drop to one-millionth of its original intensity, which corresponds to a change of 60 db. The reverberation time of a room may be computed, knowing the dimensions of the room and the acoustical absorption coefficients of the different surfaces, from

$$T = \frac{0.049V}{A \log_e \left(\frac{1}{1-\alpha} \right)} \quad (1)$$

where T is the reverberation time in seconds, V is the volume of the room in cubic feet, A is the total surface area in square feet, α is the average absorption coefficient of the room and is equal to $(A_1\alpha_1 + A_2\alpha_2 + \dots) / (A_1 + A_2)$, and α_1 is the absorption coefficient of area A_1 .

This expression may be simplified into an approximate expression accurate enough for the calculation of reverberation time of most rooms

$$T \cong 0.049 \frac{V}{a} \quad (2)$$

where V is the volume of the room in cubic feet and a is the number of absorption units in the room computed by adding the absorption of each surface: $a = A_1\alpha_1 + A_2\alpha_2 \dots$

Two nomographs have been designed to facilitate rapid calculations of reverberation time. The number of absorption units in a room may be found by using the acoustical absorption nomograph in Fig. 1. Then, knowing the absorption units and the

FIG. 1—Acoustical absorption nomograph based on $a = A\alpha$, where α is the acoustical coefficient of the material

volume, the reverberation time is given by the reverberation-time nomograph in Fig. 2.

Example

Find the reverberation time of a room 9 ft wide and 12 ft long, with a ceiling height of 8 ft. The walls and ceiling are of plaster on wood lath. One wall has a window 4 ft by 5 ft. Another wall has a glass door

3 ft by 7 ft. The floor is covered with a pile carpet on 1/2-in. felt. One adult person is in the room.

(a) Compute areas in sq ft, as follows:

$$\text{Carpet } 9 \times 12 = 108 \text{ floor}$$

$$\text{Glass } 4 \times 5 = 20 \text{ window}$$

$$3 \times 7 = 21 \text{ door}$$

41

$$\text{Plaster } 9 \times 12 = 108 \text{ ceiling}$$

$$(8 \times 12) - 21 = 75 \text{ wall minus door}$$

areas of materials in room are measured and number of absorption units of each material is found with first nomograph. Total absorption units are then combined with room volume on second nomograph to obtain directly the reverberation time in seconds

FIG. 2—Reverberation time nomograph, based on $T = 0.049 V/a$. From Fig. 1, a may be obtained graphically

$9 \times 8 = 72$ wall
 $9 \times 8 = 72$ wall
 $(8 \times 12) - 20 = 76$ wall minus window

 403

Compute absorption units, by laying a straightedge between 403 on the area scale and 1 on the material scale of the absorption nomograph in Fig. 1. Read the answer of 58.3 absorption units at the inter-

section of the straightedge with the absorption-units scale. (The range of this nomograph can be extended by multiplying the area scale and the absorption-unit scale by the same factor, such as 10. For example, to find the absorption units of the carpet area of 108 sq ft, connecting a line between 108 on the area scale and carpet pile of $\frac{1}{8}$ -in. felt on the material scale

gives 4.0 absorption units. Multiplying 4.0 by a factor of 10 gives the answer of 40.0 absorption units.)

Similarly, 13.3 absorption units are obtained for 403 sq ft of plaster on wood lath, and 3.8 absorption units constitute the allowance for one person. Adding then gives a total of 58.3 absorption units.

(c) Compute volume of room: $9 \times 12 \times 8 = 864$ cu ft.

(d) Compute reverberation time by laying a straightedge between 864 on the volume scale and 58.3 on the absorption-units scale of the reverberation-time nomograph in Fig. 2. Read the answer of 0.72 sec at the intersection of the straightedge with the reverberation-time scale.

Extending the Range

The range of the reverberation-time nomograph may be extended by multiplying the volume and time scales by the same factor, such as 10, or by multiplying the absorption scale by a factor such as 10 and the time scale by the factor's reciprocal, 1/10.

The acoustical-absorption nomograph was designed by using acoustical coefficients for 512 cycles. For more accurate computations of reverberation time at other frequencies, acoustical coefficients for those frequencies should be employed. The effect of humidity should also be taken into consideration.

THE TABLES give the longitudinal bar and bulk velocities of sound in various solids, as well as the velocity of sound in some liquids and gases.

The effective velocity of sound, V , to be used in these calculations is a rather complex function of the exciting frequency and the shape and dimensions of the vibrating element. Very few three-dimensional elastic solid problems have been studied in detail, but the following comments may be used as a guide in obtaining an approximate value of the effective velocity in the elements of many vibrating systems.

For cylindrical elements of approximately circular or square cross-section, with free sides, the effective velocity varies with the ratio of diameter to wavelength as illustrated by Fig. 1A, where V_3 is the bulk velocity, V_1 is the long bar velocity and V_2 is the minimum velocity. For most metal backing materials the ratio V_2/V_1 is about 0.65.

FIG. 1—Variation of velocity of sound with dimensional ratios of solids

velocity of sonic or ultrasonic energy varies over a range of 50 to 1, depending on the medium. Once velocity is determined, by using the table below, the wavelength for any frequency from 10 cycles to 100 megacycles can be found on the nomograph

Variation of longitudinal velocity of degree X-cut Rochelle-salt crystal with temperature

For rectangular elements with thicknesses whose thickness is less than the width, the effective velocity for the element vibration is extension (not thickness) is with the ratio of width to length as illustrated by Fig. Crystals are usually of such that this curve is applicable. ratio V_2/V_1 can be taken as to 0.8 for most of the of crystals in general use. Constraints on the sides of the cylindrical elements have the of increasing the ratio of diameter to wavelength. Simi-constraining the sides of angular elements increases effective ratio of width to length.

The velocity for a zero diameter-to-wavelength ratio is the shear velocity, and the velocity for an infinite diameter-to-wavelength ratio is the bulk velocity.

COMBINING SOUND LEVELS

Simple nomogram dispenses with the need for log tables, decibel tables or a slide rule when determining the total acoustical power resulting from the combination of two or more sounds

By W. B. CONOVER

TWO OR MORE SOUNDS combine to give a total sound whose acoustical power is the sum of the power involved in the individual components. Since sound levels are expressed in decibels, the sound level of each component must be converted to its corresponding power ratio, added to the power ratio of the other components, and the total power ratio reconverted to decibels to determine the total sound level.

A straightedge intersecting the outer scales of the nomogram at positions corresponding to the individual sound levels db_1 and db_2 intersects the center scale at db_T , which is the total sound

level. For example, individual sound levels of 8 and 10 decibels will be found to give a total of 12.1 decibels.

Any two equal sound levels combine to produce a sound which is 3 decibels higher than either of them separately. Thus 7.5 db and 7.5 db combine to yield 10.5 db; 0 db and 0 db give 3 db.

It is necessary to choose a con-

venient reference level such that the individual components are within 10 db of it. Thus, for the total of 62 db and 67 db, a reference level of 60 db is chosen. Since the components are 2 and 7 db above this reference, the resultant 8.2 db given by the nomogram is added to the reference, giving a total of 68.2 db.

When a difference of more than 10 db exists between two sound levels, the contribution of the smaller may be neglected.

Other Uses

One component of noise can be found when the other component and the total noise are known. This is useful in correcting sound-level meter readings for ambient noise. For example, a sound-level meter shows 64.5 db in the neighborhood of a certain machine when it is operating, and an ambient noise reading of 60 db when the machine is turned off. What is the noise level at the same location due to the machine alone? Choosing 60 db as the reference level, a straightedge is aligned with 0 db (60-60) on the db_1 scale, and 4.5 db (64.5-60) on the db_T scale, giving a reading of 2.6 db on the db_2 scale. Adding this to the reference level of 60 db results in a noise level of 62.6 db for the machine alone.

When more than two sound levels are to be combined, the total of two components is determined and combined with a third component, the new total combined with a fourth component, and so on. This same process may be employed to determine, in decibels, the rms value of a complex voltage or current wave when its harmonics are expressed in decibels.

MINIMUM-LOSS MATCHING PADS

A simple nomograph gives the two resistance values needed in an L-type network for matching unequal impedances with minimum power loss, and also gives directly the amount of loss in db. Multiplying factors are easily used to extend ranges

A TWO-RESISTANCE network for matching two unequal impedances provides proper matching with a minimum of power loss. The accompanying nomograph solves for the resistance values needed.

Example 1. Match a 72-ohm source to a 52-ohm load with a minimum of power loss. Determine the loss in db.

By **JOSEPH C. BREGAR**

Solution. Adjust a straightedge to connect 72 on the R_a scale and 52 on the R_b scale (R_a must be greater than R_b , and therefore $R_a = 72$ and $R_b = 52$). The intercept on the db loss scale

shows the matching-pad loss as 5.1 db. Next, adjust the straightedge at right angles to the loss line and through the 5.1-db point, and read the X and Y values as $X = 0.53$ and $Y = 1.9$. The desired resistor values are then $R_1 = XR_a = 0.53 \times 72 = 38$ ohms, and $R_2 = YR_b = 1.9 \times 52 = 99$ ohms.

The scale ranges are chosen for common impedance values. The nomograph may be used for any values by the application of the same multiplier to the R_a and R_b scales. No multipliers are required for the loss scale or the X and Y values. The X and Y values are applied to the original problem values of R_a and R_b in determining R_1 and R_2 .

Example 2. Match a 3,000-ohm source to a 600-ohm load with a minimum of loss. Determine the loss.

Solution. A convenient scale factor is 1/10. Applied to the problem values, R_a becomes 300 and R_b becomes 60. Connect these points with a straightedge and read the pad loss as 12.5 db. Next, read the X and Y values as 0.89 and 1.12 respectively. Applying these values to the original problem impedances of 3,000 and 600 ohms gives $R_1 = 0.89 \times 3,000 = 2,700$ ohms and $R_2 = 1.12 \times 600 = 670$ ohms.

The matching of impedances of more than 30-to-1 ratio involves high power losses, and other types of coupling networks are employed. For impedance matching when power loss is unimportant and the ratio of impedances is more than 30-to-1, the X and Y values approach 1; then $R_a = R_1$ and $R_b = R_2$ for proper matching.

DESIGN OF T PADS

Graphs for determining resistance of the three elements of dissymmetrical T-pad networks facilitate design of pads having attenuation of as much as 25 db, and impedance mismatch ratios up to 5 to 1. Graphs apply to symmetrical pads with matched loads

IN radio and communications work the necessity for pads or attenuators of definite electrical loss and definite terminal impedance often arises. It is the purpose here to facilitate the design and construction of such pads of symmetrical or dissymmetrical T configuration, through simple, rapid, graphical methods, without making necessary recourse to the usual mathematical design equations.

In the following discussion a and b will refer to the series impedances and c the shunt impedance of the three-element T network. As pads with elements other than pure resistances are seldom encountered, only the case of a pure resistance network will be discussed, although the symbol Z will be used. If a balanced pad is desired, it is necessary merely to place half of the value of a and half of the value of b in the two lower branches of the pad.

Three individual graphs are given in Fig. 1, one for each of the impedance elements in a T network. Each graph contains a family of curves, one for each of several different values of attenuation or loss in decibels. The family of curves is plotted to show the normalized resistance (for the element a , b or c of the T for which the curve applies) as ordinates, against the ratio of impedance transformation as abscissa. Since the curves are plotted for the normalized impedance of 1 ohm, the resistances found from the curves must be multiplied by the actual impedance value of the input circuit to obtain the true values of resistance for the elements of the de-

By **EDWIN Y. WEBB, Jr.**

sired T network. By plotting normalized impedances, only one set of curves is required no matter what the impedance value may be. It should be noted that while the curves are plotted for a dissymmetrical T network, which is useful in matching unequal impedances, the curves are equally useful for the symmetrical T network for matching equal impedances since in the latter case the impedance transformation is 1/1, and a and b are equal.

The graphs can be used for any impedance ratio normally encountered in practice. If an impedance ratio less than 1 is encountered, the T network can be reversed, for purposes of analysis, to obtain a transformation ratio greater than 1. The curves can of course be used for uneven ratios, such as 2.5/1 or 3.7/1. The curves can likewise be used for symmetrical T pads, for in this case the terminal impedances Z_1 and Z_2 will be alike. The network impedances a and b will also be alike, and hence we need only use the curves for determining two separate constants a and c . The curves are plotted more accurately than the accuracy of commercial resistors, and consequently errors involved from the graphical design method will be negligible for ordinary purposes. Care should be exercised in reading the curves, however, to ascertain that the scales are not misinterpreted.

Note that the actual values of

Z_1 and Z_2 (the terminal impedances) do not affect in any way whatever the values used in plotting the curves as only their ratios were used. Therefore, for a 10-db pad with terminal impedances of 5 and 10 ohms the identical points on the curves will be used as if the terminal impedances were 300 and 600 ohms, as in both cases the ratio of Z_2 to Z_1 is 2 to 1.

The loss of the pad is obtained by calculating the ratio of the power transferred from Z_1 to Z_2 with the pad in the circuit and again with the pad removed from the circuit. Assuming 1 volt applied, and impedances of 100 and 200 ohms, the power transferred when the pad is out of the circuit is

$$P_o = I^2 R = \left(\frac{1}{300}\right)^2 \times 200$$

With the pad in the circuit, the power absorbed by Z_2 is

$$\begin{aligned} P_i &= I^2 R \\ &= \left[\left(\frac{1}{200}\right) \left(\frac{99.2}{200 + 145 + 99.2}\right) \right]^2 \times 200 \\ &= \left[\left(\frac{1}{200}\right) \left(\frac{99.2}{444.2}\right) \right]^2 \times 200 \end{aligned}$$

The loss in decibels is then

$$\begin{aligned} db &= 10 \log_{10} (P_o/P_i) \\ &= 10 \log_{10} \left[\frac{\left(\frac{1}{300}\right)^2 \times 200}{\left[\left(\frac{1}{200}\right) \left(\frac{99.2}{444.2}\right) \right]^2 \times 200} \right] \\ &= 10 \log_{10} \left[\left(\frac{200}{300}\right) \left(\frac{444.2}{99.2}\right) \right]^2 \\ &= 9.5 \text{ db.} \end{aligned}$$

Hence, the terminal impedances as calculated from the graphs are correct. The loss of the network is actually 9.5 db instead of the 10 db for which it is designed, but the error is sufficiently small to be neglected for nearly all practical purposes.

FIG. 1—To use the graphs it is necessary to know: (1) the attenuation or loss, in decibels, which the network is to provide; (2) the impedance Z_1 , from which power is fed to the T attenuator, and (3) the impedance Z_2 , into which the T network feeds. The first condition specifies the network loss, and hence indicates which curve of the three families is to be selected for any particular problem. The second and third conditions determine the impedance transformation ratio, and hence determine at what point on the abscissa the graph is entered. From this point of entry, project vertically upward until the desired curve is reached; then project to the left and read the normalized resistance for the specified conditions for the element for which the chart applies. Multiply this reading by Z_1 to obtain the true resistance of the element for the specified conditions

DESIGN OF LOUDSPEAKER DIVIDING

Four-parameter chart gives directly the required values of L and C for a parallel-connected constant-resistance dividing network, at any desired crossover frequency and line impedance, when separate low and high-frequency loudspeakers are employed

FIG. 1—Ideal transmission characteristics of a 1,000-cycle dividing network

FIG. 2—Circuit of parallel-type constant-resistance dividing network, with design equations (L is in henrys, C is in farads, f is crossover frequency in cycles, and R_0 is impedance in ohms of input and each output branch of the network)

By EARL R. SCHULER

WITH divided-range loudspeaker systems, an electrical dividing network must be used to separate the low and high frequencies into two bands so that each may be reproduced by the proper loudspeaker unit. To approximate the ideal network transmission characteristics of Fig. 1, the parallel-type constant-resistance dividing network of Fig. 2 is favored for its simplicity since both inductors (and both capacitors) have the same values.^{1,2} The chart in Fig. 3 gives these values of L and C directly for various values of

crossover frequency f and line impedance R_0 .

Although the values of L and C may be computed easily from the simple formulas given in Fig. 2, the chart will be found very useful for preliminary design problems. The chart may be used beyond the ranges shown by employing one of the following sets of multiplying factors for the scales:

R_0	f	L	C
1	10	0.1	0.1
10	1	10	0.1
10	10	1	0.01

To prevent the generation of harmonics and intermodulation products by the network, the inductance of the coils must be independent of the signal level. Since air-core inductors are inherently free of this difficulty they are usually preferred over iron-core types. They must be rather large, however, and must be wound with heavy wire in order to obtain a reasonably high Q . A value of 20 at the crossover frequency is satisfactory. Information on the design of air-core inductors may be found in the literature^{3,4}.

EXAMPLE 1: A dividing network is required for use in a 15-ohm line, the crossover frequency to be 1,000 cycles. From the point of intersection of the diagonal 15-ohm and 1,000-cycle lines on the chart, read out to the left and upper edges of the chart to the values 3.37 mh and 7.50 μ f for L and C . Coils may be wound especially for this value,

and standard-size capacitors may be connected in parallel to make up the required capacitance within 5 to 10 percent.

It is permissible to redesign the network for a slightly different crossover frequency to permit use of standard capacitors. New values taken off the chart, starting from the intersection of the 15-ohm and 8- μ f lines, are 938 cycles and 3.60 mh.

EXAMPLE 2: A dividing network is required for use in a 600-ohm line, the crossover frequency to be 500 cycles. This installation will require the use of separate autotransformers to match the low- and high-frequency units to the 600-ohm outputs of the network. Since 600 ohms does not appear on the chart, preliminary values must be determined from the intersection of the 60-ohm and 500-cycle lines; these are found to be 27 mh and 3.75 μ f. Since the value for R_0 must be multiplied by 10 and there is no change to be made in the frequency (f multiplied by 1), the conditions for determining the final values are met by applying the multiplying factors on line 2 of the table. This gives final values of 600 ohms, 500 cycles, 270 mh, and 0.375 μ f for the network.

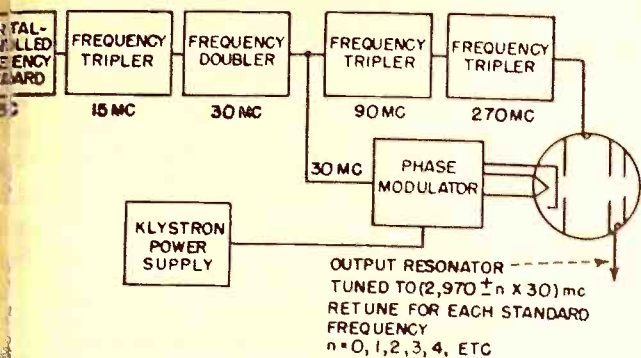

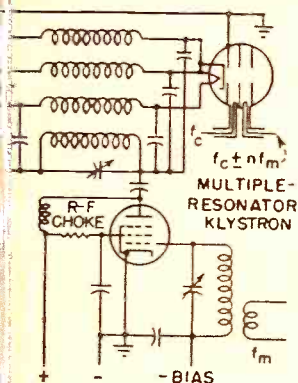

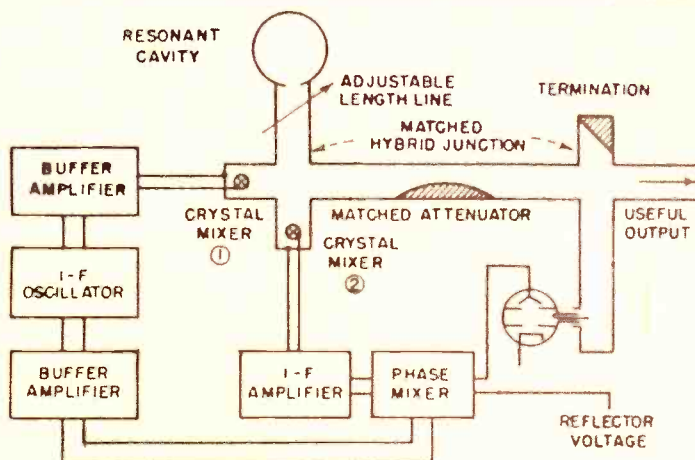

Chart giving values of L and C for desired crossover frequency and line impedance in a parallel constant-resistance network

FREQUENCY STANDARD—A phase-modulated signal derived from the same source as the input signal for a klystron frequency multiplier can be used to generate standard frequencies in the microwave region. Modulator unit is similar to that shown for phase-modulation of a klystron amplifier. The klystron multiplication factor is 11. The choice of 270-mc input frequency and 30-mc modulation frequency requires only four sidebands to cover the frequency spectrum between harmonics. For example, the next standard frequency above $2,970 + 120$ mc is a sideband of the 12th harmonic of the input frequency, or $3,240 - 120$ mc

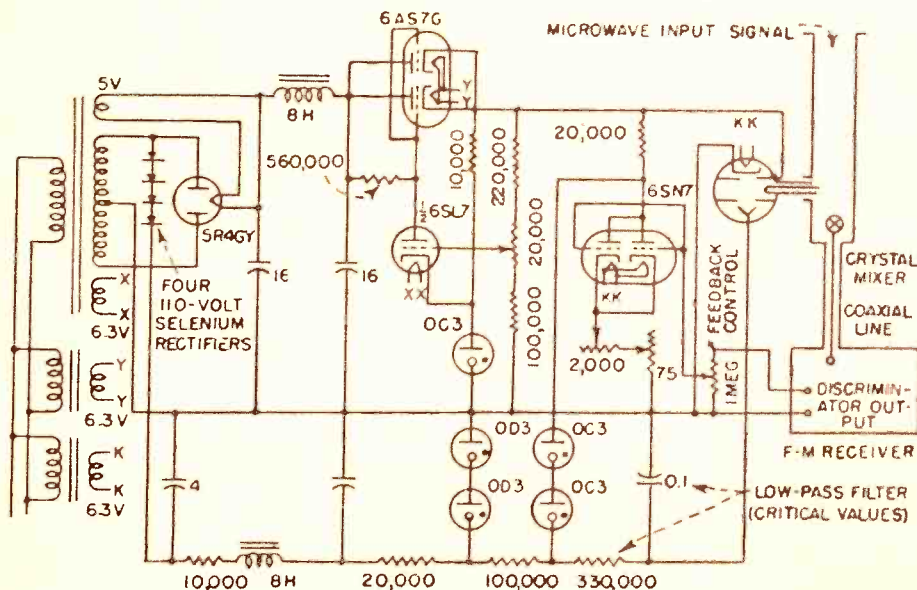

RESONANT CAVITY CONTROL OF REFLEX OSCILLATOR—Frequency stabilization of a reflex klystron oscillator can be achieved by locking the oscillator to a resonant cavity. A block diagram of a method developed by R. V. Pound is illustrated. A hybrid junction (magic tee) provides a sample of the output of the reflex klystron oscillator. When the oscillator frequency coincides with the resonant frequency of the cavity there is no signal at mixer crystal No. 1 and no i-f signal at mixer No. 2. A drift in frequency produces an r-f signal at the first crystal which becomes modulated at the intermediate frequency and is reflected to the second mixer where it is demodulated to produce an i-f signal. The phase and amplitude of the demodulated i-f signal are determined by the relation between the klystron frequency and the cavity frequency. The phase mixer compares the demodulated i-f with the original source and produces a signal which corrects the klystron frequency

PHASE MODULATION OF KLYSTRON AMPLIFIER—Some microwave transmitter systems can advantageously use phase modulation, either as a device for modulating a klystron amplifier or as a means of producing two signals with a fixed frequency difference. In most cases the modulation frequency f_m is made high enough so that a sideband can be separated from the carrier frequency f_c by the selectivity of the high-Q output resonator. The problem is to vary the entire

electron gun structure, which is at a high d-c voltage above ground, at an r-f rate. Since r-f chokes for the heater leads are not too practical, the scheme illustrated for including the three klystron leads as part of the plate tank circuit has been devised. The klystron leads are wound with the same number of turns as an integral part of the tank coil but insulated adequately for the cathode voltage on the klystron. The r-f circuit must be kept close to the klystron socket

Reflex klystron oscillators are well suited to automatic frequency control in f-m systems because the d-c voltage of the discriminator can be applied to the reflector electrode to control the frequency of the local oscillator. The r-f voltage supply in this circuit is derived from a selenium rectifier so a common grounded lead can be connected to the cathode of a type 723 similar reflex klystron local oscillator. Two VR-tube regulators in series provide adequate voltage stability for this application. The output of the f-m discriminator is connected to the grid of a buffer amplifier which controls the reflector voltage. The 2,000-ohm and 75-ohm variable resistors in the cathode lead act as coarse and fine controls of the average reflector voltage

VHF FIELD INTENSITIES

Nomograph shows fields in microvolts per meter for transmitter powers up to 500 watts, antennas up to 500 feet, over obstructions as high as 10,000 feet in the frequency range between 20 and 260 mc

By E. A. SLUSSER

IN PLANNING a new vhf point-to-point radio circuit, it is first necessary to make some estimate of the expected transmission between the two points in question in order to determine the feasibility of such a circuit.

Likewise, in planning a new vhf mobile system the expected coverage over flat land and into shadowed areas must be predetermined. These estimated transmission figures can be used to assist in the selection of equip-

ment and location of transmitter sites. Such estimates are usually made by means of profile maps and transmission nomographs.

Previous nomographs for estimating field intensities in the vhf frequency range have been made for small segments only of the total band of frequencies, thus necessitating several charts to cover the entire band. This nomograph enables one to select a given frequency in the range between 20 and 260 mc and estimate the field intensity for either transmission over smooth land or transmission over paths involving shadow losses. It assumes either horizontal or vertical polarization over land and horizontal polarization over sea water. It also assumes 50-watt transmitters and half-wave antennas elevated 40 feet above the ground, but supplementary conversion data is given for other powers and antenna heights.

To use the nomograph, it is necessary to draw an elevation profile of the intervening terrain between the two proposed station sites. An example is shown in Fig. 1. A triangle is constructed by drawing two lines from the station sites, X and Y, each tangent to the nearest hill or obstruction that blocks the line-of-sight path. A base line is also drawn to intersect the two sites, and a vertical line is drawn through the apex of the triangle and intersecting the base line.

The information taken from this figure includes: D_1 , which is always the shortest distance in miles from one of the station sites to the vertical line; H , which is the height in feet along the vertical line between the apex of the triangle and the intersection of the base line; and the total transmission distance D . This information, along with a given frequency F in the vhf range, can be applied to the nomograph. The steps follow:

(1) A point on graph 1 is

FIG. 1—Sample elevation profile used with nomograph

ed representing (F, D), this point is projected horizontally to a point on scale A. H is determined and a line is constructed through H to the point on scale A. This line intersects B at some point.

A point representing the frequency and the total distance (D) is determined on graph and this point is projected vertically to scale C.

A line is constructed passing through the points on scales C and intersecting scale D.

The estimated field intensity in db, referred to one microvolt per meter, is taken at the point where this line intersects scale D.

For estimating field intensity on smooth land, scale A is not used and H is taken as being

the transmission estimates by use of this nomograph based on standard conditions. The data that are obtained are in general agreement with the data for smooth or moun-

tainous terrain. The factors affecting vhf transmission are both natural (such as meteorological effects, type of soil and surrounding vegetation) and artificial (for example, antenna height, antenna gain, transmitter power and transmission-line loss). The latter items can be taken into consideration when making an estimate and a new equivalent field intensity (equivalent on the basis of a half-wave antenna) can be found.

A sample calculation can be made between locations X and Y by using the profile given in Fig. 1. Assume the following: at the transmitter end a 100-watt 150-mc transmitter using a three-element parasitic antenna having a gain of 6 db mounted on a 90-foot pole; on the receiving end another three-element 6-db-gain antenna mounted on a 30-foot pole; a combined transmission-line loss of 3 db at both ends. The answer is +14.5 db.

By comparing the estimated data with the receiver input level

Fig. 2—Conversion graph for antenna elevation and transmitter power

I—Expected Circuit Performance With Average Receiver

Frequency Range in Mc	Equivalent estimated field intensity in db referred to $1\mu\text{V}$ per meter		
	Probably Unsatisfactory	Questionable	Probably Satisfactory
20-40	< -5db	-5 to +5db	> +5db
40-70	< 0	0 to +10	> +10
70-100	< +5	+5 to +15	> +15
100-120	< +10	+10 to +15	> +15
120-160	< +10	+10 to +20	> +20
160-220	< +15	+15 to +20	> +20
220-260	< +15	+15 to +25	> +25

FIG. 3—Conversion graph for receiver input voltage

requirements one can determine whether or not the circuit will be probably satisfactory. For the average receiver the performance can be taken from Table I.

In making the above comparison one must take into consideration the amount of man-made noise present in the receiver area. The above figures are based on average noise conditions but in extremely noisy areas it may be necessary to increase the figures by about 20 db.

In order to compare the above data with receiver sensitivity, it may be desirable to convert field intensity, which is given in terms of db above one microvolt per meter, to microvolts appearing at the receiver terminals. This can be done by means of Fig. 3. This figure assumes a half-wave antenna connected to the receiver terminals (72 ohms input) by means of a zero-loss transmission line. The voltage (for half-wave antennas) appearing on the receiver terminals is $0.32LE$ where L is the length of the antenna in meters and E the field intensity in microvolts per meter.

For the previous example, +14.5 db equivalent field intensity at 150 mc corresponds to approximately 1.7 microvolts at the receiver terminals.

HIGH-PASS, LOW-PASS and BAND-PASS

Rearrangement of equations and accompanying charts permit design of multi-section filters with only two or at most three settings of a reactance slide rule. Filter component values are specified as functions of midband frequency and terminating impedance

By G. J. MERCHANT

MUCH of the drudgery in designing high-pass and low-pass filters for audio frequencies may be eliminated by the simple expedient described here.

The formulas for L and C in a single constant- k high-pass T-section are $L = R/4\pi f_0$ and $C = 1/\pi f_0 R$ where f_0 is the cut-

off frequency and R is the terminating resistance. A simple rearrangement of these expressions gives $2\pi(f_0/R)L = \frac{1}{2}$ and $1/2\pi(f_0 R)C = 1$, or, in other words, L is the inductance whose reactance at the frequency f_0/R is equal to $\frac{1}{2}$ ohm, and in a similar manner C is the capacitance whose reactance at the frequency

$f_0 R$ is found to be equal to 1 ohm.

The method can be extended to other types of sections, and a multisection filter can be designed with only two settings of a reactance slide rule, once at f_0/R for the inductances and once at $f_0 R$ for the capacitances. In multisection filters the sharpest cutoff consistent with high attenuation outside the pass band is realized by using terminating m -derived half-sections with $m = 0.6$, a full m -derived section with $m = 0.8$, and one or more constant- k sections.

Figure 1 gives the values of the reactances in ohms in such sections, the coils being evaluated at f_0/R and the capacitors at $f_0 R$.

For example, to design a three-section low-pass filter of T-sections with $R = 500$ ohms and $f_0 = 1,000$ cps, find on the slide rule that $f_0/r = 1,000/500$ or 2 cps. Also on the slide rule, find the inductance whose reactance at 2 cps is the value given in Fig. 1. Then determine $f_0 R$ to be $1,000 \times 500$ or 500 kc and find the capacitance whose reactance at 500 kc is the value given in Fig. 1. The complete filter and its attenuation characteristic are given in sections A and B of Fig. 2.

Low-pass or high-pass filters can be completely specified in terms of two quantities, the cutoff frequency and the terminating impedance. Band-pass filters introduce an additional

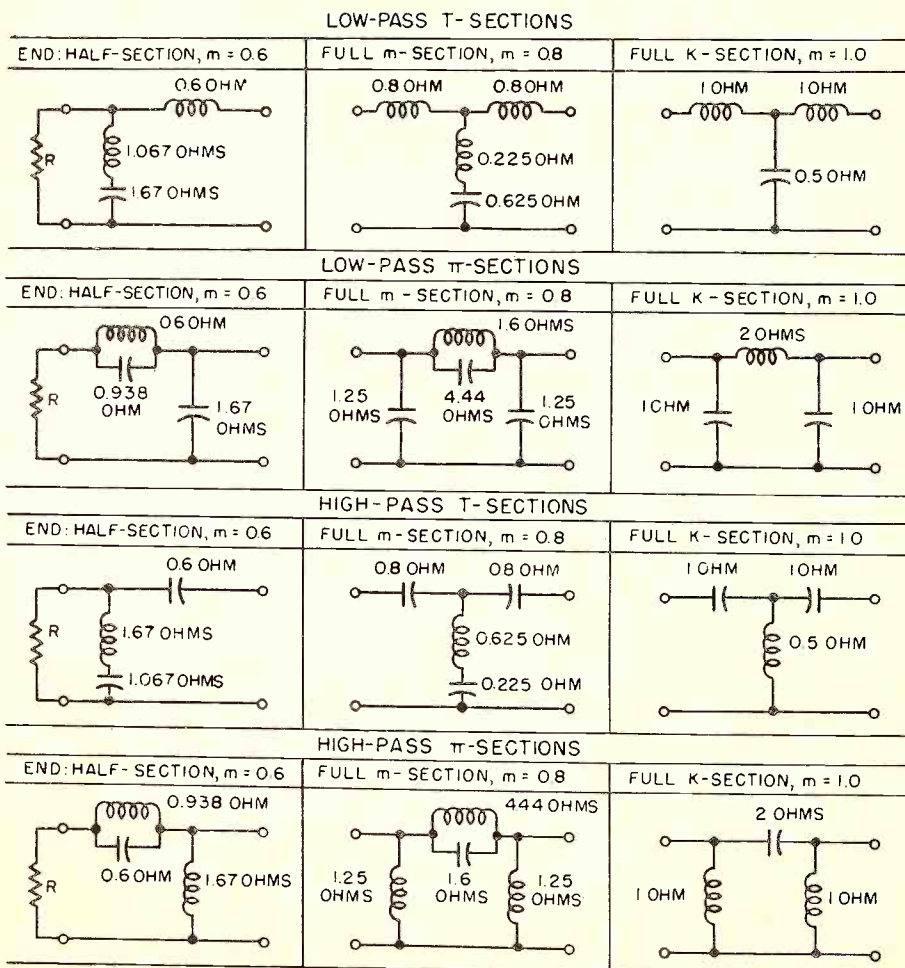

FIG. 1—Generalized impedance chart from which impedances are calculated by reactance slide rule if terminating impedance and cutoff frequency are given

FILTER DESIGN

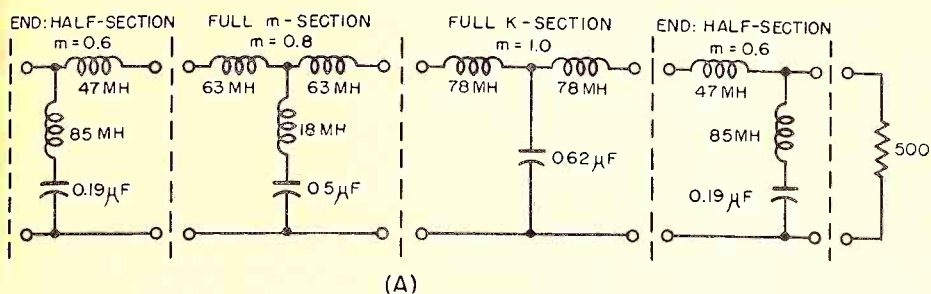

FIG. 2—Illustrative filter design values and attenuation characteristics of low-pass filter designed by use of Fig. 1

ty, the bandwidth, and more require three quantities to specify their performance but their calculation can be simplified by means of the technique used for low and high-pass

charts* in Fig. 3 give the impedance constants, in ohms, and π band-pass sections in terms of the terminating impedance R , the upper cutoff frequency f_2 , and the midband frequency f_m , which is the geometric mean of the upper and lower cutoff frequencies and is given by $f_m = \sqrt{f_1 f_2}$.

For example, to design a π band-pass filter of π -sections with upper and lower cutoff frequencies at 770 cps and 1,300 cps and terminated in 1,000 ohms, first find $f_m = \sqrt{770 \times 1,300} = 1,000$ cps. Then find $f_2/f_m = 1,300/1,000 = 1.30$. Then find $f_1/f_m = 770/1,000 = 0.77$, and the inductances whose reactance in ohms at 1 cps are the values given on the chart opposite $f_2/f_m = 1.30$. Then find $X_L = 1,000 \times 1.30 = 1,300$ ohms and the capacitances in like units.

When f_2/f_m is greater than 1.0, the filter can be more economically designed by cascading π and T high-pass sections whose passbands overlap. In specifying values for the filter design, elements appearing directly in parallel or in series after cascading should be indicated.

TRANSMISSION LINES

oltage, current and resistance along ideal or low-loss resonant lines are conveniently portrayed, together with equivalent resonant circuit at quarter-wave sections and reactance for other lengths of open or shorted lines

THE important part which transmission lines play in modern radio communication makes it useful to have available in compact form for ready reference a graphical interpretation of the behavior of such lines. For simplicity of presentation, the curves and diagrams have been plotted on the assumption that the lines are free from loss. The presence of a slight amount of attenuation will not appreciably affect the general shape of the curves, and hence the diagrams are useful for practical applications as well as for the ideal loss-free case. If the line has appreciable attenuation, however, the curves shown here must be modified slightly to apply to actual condi-

tion. In drawing the curves, the line is assumed to be fed from a generator whose output impedance is equal to the characteristic impedance of the line. With this assumption, the wave is absorbed and dissipated and is not reflected from the sending end. The curves are drawn for lines whose distant ends are open or shorted, corresponding to infinite and zero resistance termination at the far end.

The data for which the curves have been compiled are available at a glance. For example, the length of line required to give a high impedance, a low impedance, an inductive reactance or a capacitive reactance is directly evident.

Starting from top to bottom, the chart shows the following information for transmission lines:

1. *Reactance curves for lines of various lengths.* While the curves shown apply for lines whose length is one wavelength or less,

the curves are periodically repetitive, and hence may be extended to lines of any length. For lines longer than one wavelength, it is convenient to determine the line characteristics by subtracting an integral number of wavelengths from the line. The remaining length of line will then be less than one wave in length, and its characteristics may then be determined from the graphs.

The electrical equivalent reactance for lines of various lengths between exact multiples of a quarterwave line. When the reactance curve is positive, the electrical equivalent reactance is inductive, whereas it is capacitive for lines of such length that the reactance curve is negative. The ideal line, free from attenuation, behaves either as a pure inductive reactance or as a pure capacitive reactance within any given quarterwave section. Actual lines, in which some attenuation is present, will also show a resistive component as well as the reactive component, but this is not indicated on the diagram.

The resonant circuit characteristics of the line at exactly each quarter wavelength. The ideal line behaves as a series resonant circuit and as a parallel resonant circuit alternately every quarter of a wave long. In the ideal case the line has zero resistance when the series resonant circuit is used to represent it, and has infinite impedance for those quarter-wavelengths for which it behaves as a parallel resonant circuit. Actu-

ally, real physical lines have more than zero and less than infinite resistance at these points. The line is resonant at 90-degree intervals for both open and shorted cases, and for quarter-wave intervals the line behaves alternately as a series and as a parallel resonant circuit.

The resistance and the voltage and current distribution for open and shorted lines. For convenience the resistance curve is plotted along with the voltage and current distribution along the length.

For the shorted line, the graphs show that, as measured from the shorted end, the line acts first as an inductance for the first quarter-wave section, then as a capacitance for the next quarter-wave section, and so on, alternately for each 90-degree interval.

For the open-end line, the graph shows that, as measured from the open end, the line acts first as a capacitance and then as an inductance, alternately, for each quarter-wave section.

The quarter-wave diagram near the bottom of the charts show that a quarter-wave section of line may be considered as a tuned circuit. If the line is slightly less than a quarter-wave, it will present inductive reactance, whereas if it is slightly longer than a quarter-wave, the section will assume the characteristics of a capacitance.

In a similar manner, the lowest diagram shows that a half-wave line may be considered as a tuned circuit element. If the line is slightly less than a half-wave long, its reactance will be inductive, whereas the reactance will be capacitive if the line is slightly longer than a half-wave.

TEN R-F TRANSMISSION LINE

Ten equations commonly used to compute relationships between electrical and mechanical properties of radio-frequency transmission lines have been converted to convenient nomographs covering both two-wire and coaxial lines for frequencies up to 20,000 mc

By PHILLIP H. SMITH

TEN of the most useful transmission-line equations have been plotted as nomographs as a convenience to the radio engineer. The derivation of the formulas is based upon certain simplifying assumptions which are generally considered justifiable for r-f lines.

1. *Characteristic Impedance of Transmission Lines.* For radio-frequency transmission lines where the losses per wavelength are relatively small, the characteristic impedance is essentially a pure resistance. The characteristic impedance is numerically equal to the square root of the ratio of the distributed inductance to the distributed capacitance per unit length. Since both of these parameters are uniquely related to the physical size and spacing of the conductors, it is possible to express the characteristic impedance in terms of the physical dimensions of the line.

Thus, the characteristic impedance Z_0 in ohms of an open 2-wire line is

$$Z_0 = 276 \log_{10} (2D/d) \quad (1)$$

where D is the wire separation on centers and d is the wire diameter, both in the same units. Figure 1 shows the characteristic impedance of an open 2-wire line as a function of the conductor dimensions and their center-line spacing.

2. *Characteristic Impedance of a Coaxial Line.* The characteristic impedance Z_0 in ohms of a coaxial transmission line is

$$Z_0 = 138 \log_{10} (D/d) \quad (2)$$

where D is the inner diameter of

the outer conductor and d is the outer diameter of the inner conductor. This applies only to a line where the medium between conductors is predominantly a gas, such as air, at low pressures.

If the coax line is filled with a uniform dielectric material other than a low-pressure gas, the characteristic impedance is reduced by a factor equal to $1/k^2$, where k is the relative dielectric constant of the material. For a line with bead insulators at small uniform intervals, the

effective dielectric constant k_e may be computed from

$$k_e = (k t + s)/(t + s) \quad (2a)$$

where t is the thickness of one bead and s is the spacing between two beads, both t and s being in the same units, and k is the relative dielectric constant of the bead.

A number of optimum values for the characteristic impedance of coaxial lines exist which are based upon different considerations such as the maximum power handling capability and

FIG. 1
CHARACTERISTIC IMPEDANCE
OPEN WIRE LINES

NOMOGRAPHS

minimum loss. Several of optimum values are indicated along the characteristic impedance scale on the right side of the nomograph. Generally, all of these optimum values are relatively broad in characteristics and a considerable departure can generally be tolerated for any particular application.

Figure 2 shows the characteristic impedance of a gas dielectric coaxial transmission line as a function of the two conductor diameters.

High-Frequency Resistance of Coaxial Line. The high-frequency resistance of a coaxial transmission line is one of the principal factors which determine the attenuation along the line. It is also one of the factors which determine the maximum anti-resonant imped-

ance and the minimum resonant impedance of a line section when used as a circuit element. The high-frequency resistance of a coaxial line is a function of both conductor dimensions and of the frequency (due to skin effect). It is also a function of the resistivity of the material of which the conductors are made.

For copper coaxial lines the high-frequency loop resistance R in ohms per 1,000 feet is

$$R = 0.0315 f^{1/2} \left[\frac{1}{d} - \frac{1}{D} \right] \quad (3)$$

where f is the frequency in kilocycles, D is the inner diameter of the outer conductor in inches, and d is the outer diameter of the inner conductor in inches.

For conductors other than copper, the high-frequency resistance is proportional to the square root of the ratio of the

resistivity of the conductor to that of copper.

Figure 3 shows the resistance of a copper coaxial line as a function of the conductor dimensions and the frequency. Dielectric losses, which are negligible in a gas dielectric line, are not included.

The nomograph in Fig. 3 is used as follows: draw a straight line connecting points on the first and fourth scales from the left, which show, respectively, the line conductor diameters. Obtain the intersection of this line with the second scale, marked Size Factor. Now project this intersection to a corresponding point on the third scale, marked Pivot Line, as shown in the example on the nomograph. Finally, connect this new pivot point with a straight line intersecting the desired value on the sixth or frequency scale. The intersection of this latter straight line with the scale marked Resistance in ohms per 1,000 feet gives the desired loop resistance value.

4. *Conversion of Loss Resistance to Decibels Attenuation per Unit Length.* It is sometimes convenient to convert loop resistance of a transmission line (as obtained from Fig. 3) to decibels (db) per unit length. This may be done if the characteristic impedance of the line is known. The conversion equation is simply

$$\text{db} = R/0.23025 Z_0 \quad (4)$$

where R is the loop resistance and Z_0 is the characteristic impedance. This relationship is plotted on the nomograph of Fig. 4. The nomograph applies to either open-wire or coaxial lines and does not require the line conductors to be of copper.

5. *Antiresonant Impedance of a Transmission Line Section.* The antiresonant impedance Z_{AR} of a transmission line section either open or short-circuited at its far end is a function of the

FIG. 2
CHARACTERISTIC IMPEDANCE
COAXIAL LINES

Ten R-F Transmission Line Nomographs (continued)

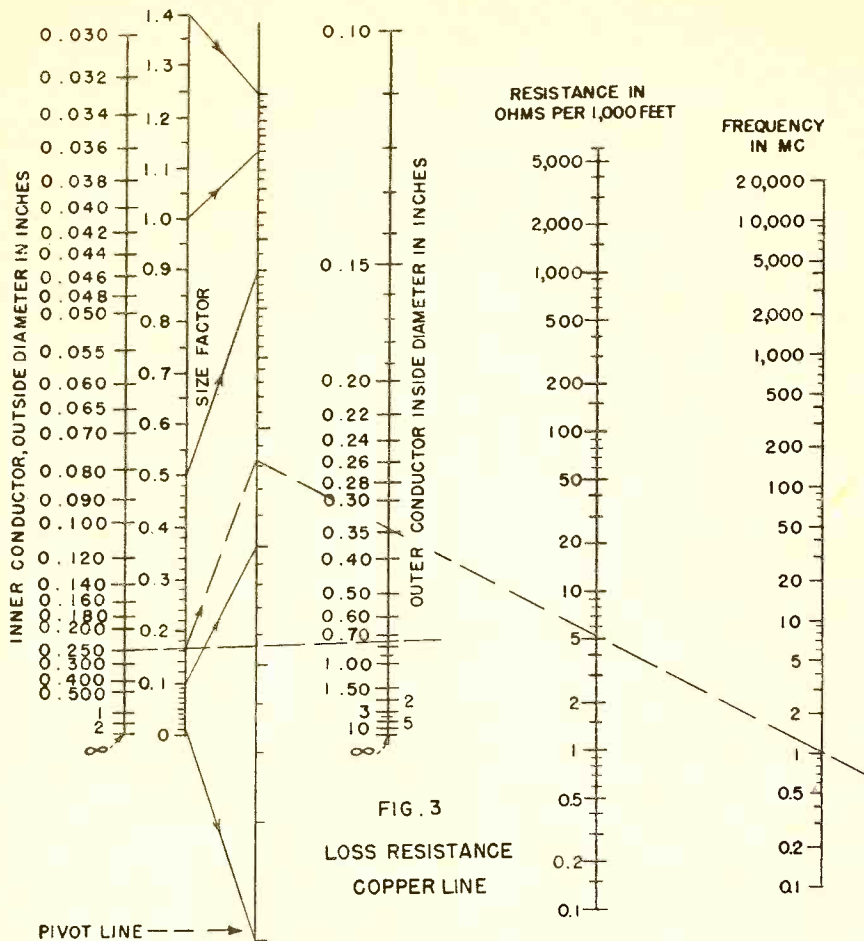

FIG. 3
LOSS RESISTANCE
COPPER LINE

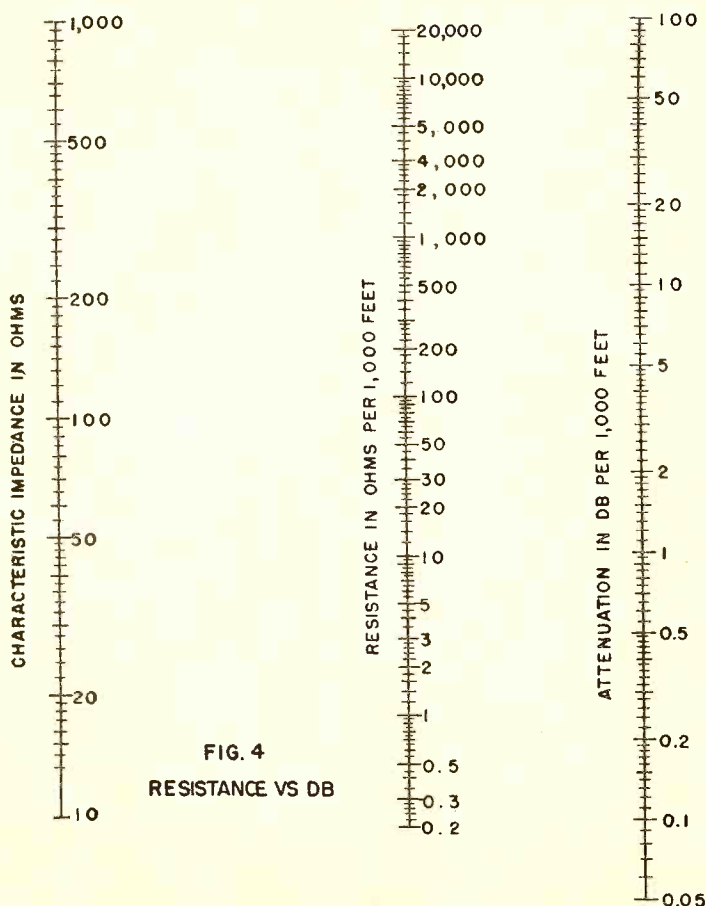

FIG. 4
RESISTANCE VS DB

total conductor resistance and the characteristic impedance of the section. The relationship is

$$Z_{AR} = 2 Z_0^2 / R \quad (5)$$

where Z_0 is the characteristic impedance and R is the resistance of the antiresonant line section.

The shortest antiresonant line section is one-quarter wavelength long (short-circuited at its far end) and accordingly this will have the highest antiresonant impedance. A line section one-half wavelength long (open-circuited at the far end) will have only half as high an antiresonant impedance because its resistance R is twice as great.

Figure 5 shows the antiresonant impedance of a transmission line as a function of the total resistance and the characteristic impedance of the section. The nomograph applies equally to either coaxial or open-wire lines.

The resonant impedance of a transmission-line section is simply one-half of its total resistance (obtained from Fig. 3); accordingly, no nomograph has been plotted for this.

6. Input Reactance of a Transmission-Line Section. A short length of transmission line is sometimes used as a reactance element in high-frequency circuits. The input reactance is a function of the electrical length of the line section and its characteristic impedance. The reactance varies between values essentially equivalent to plus and minus one half of the antiresonant impedance (obtained from Fig. 5). In air or gas dielectric coaxial lines, the electrical length is very nearly the same as the physical length measured in terms of free space wavelengths. A dielectric other than a gas results in a reduction in the length of the wave in the line which is proportional to the square root of the average dielectric constant. Thus a polyethylene coaxial cable with a dielectric constant of 2.5 will be electrically $(2.5)^{1/2}$ or 1.6 times as long as if the dielectric were a gas.

The electrical length and the characteristic impedance of a section as well as its termination (either open circuit or short circuit) determine the magnitude and sign of the input impedance. For an open-wire or coaxial line section, open-circuited at its far end, the input impedance X_i in ohms is

$$X_i = -Z_0 \cot(360 l/\lambda) \quad (6)$$

where l/λ is the electrical length in wavelengths and Z_0 is the characteristic impedance.

For an open-wire or coaxial line section, short circuited at its far end, the input reactance X_i in ohms is

$$X_i = Z_0 \tan(360 l/\lambda) \quad (6a)$$

Figure 6 shows the input reactance of an open or short-circuited transmission-line section as a function of the electrical length, the characteristic impedance, and the termination.

Quarter-Wave Transmission-Line Impedance Transformers
Impedance transformers are made along radio-frequency transmission lines by employing a quarter-wave section of transmission line of selected characteristic impedance as an impedance transformer. When a line section is terminated in a pure resistance its input impedance will be a pure resistance and depends upon the load resistance value and the value of characteristic impedance of the quarter-wave line section.

Figure 7 shows the input reactance R_i in ohms of a quarter-wave open-wire or coaxial line terminated in a pure resistance load. The relationship is

$$R_i = Z_0^2/R_l \quad (7)$$

where R_l is the terminating resistance and Z_0 is the characteristic impedance.

Current-Phase Relationship in a Transmission Line. The relationship of the current point to point along a radio-frequency transmission line will be uniform with length when the line is terminated in an impedance equivalent to the characteristic impedance;

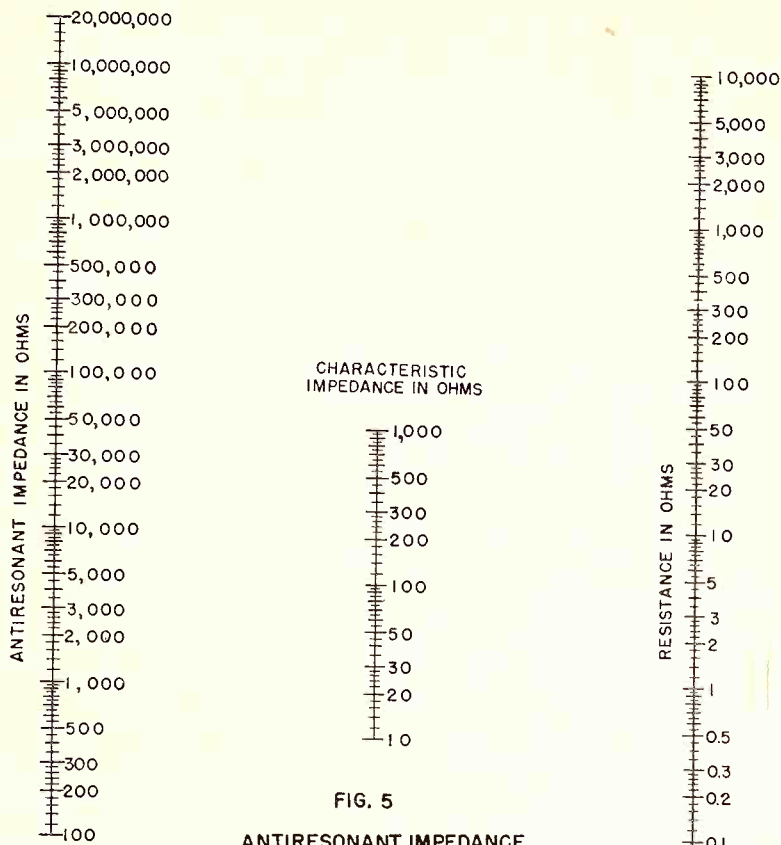

FIG. 5

ANTIRESONANT IMPEDANCE

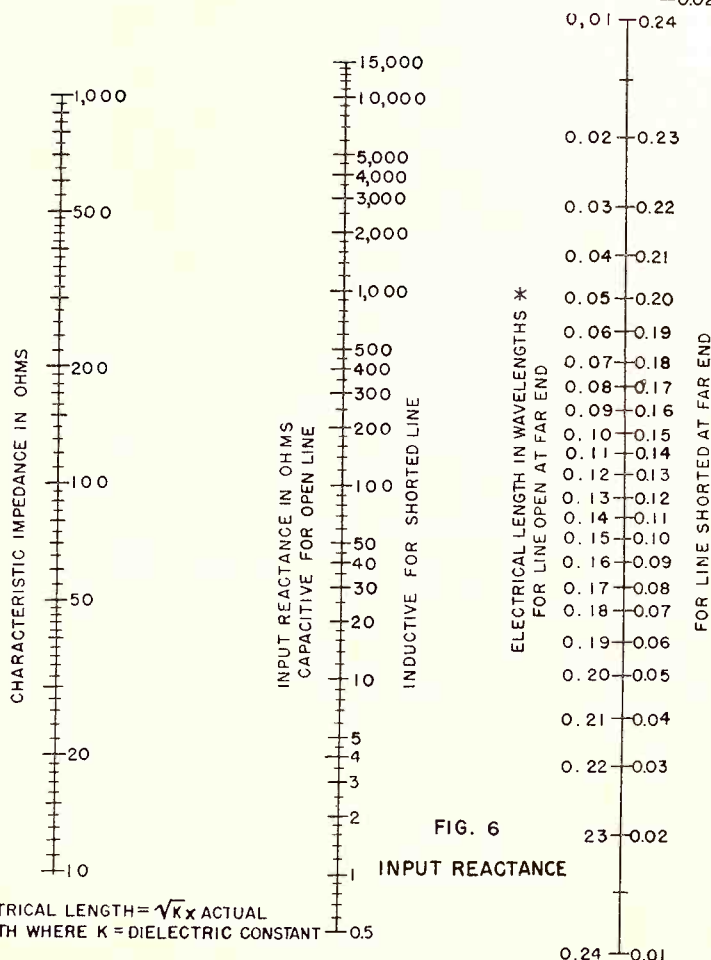

FIG. 6

INPUT REACTANCE

* ELECTRICAL LENGTH = $\sqrt{K} \times$ ACTUAL LENGTH WHERE K = DIELECTRIC CONSTANT

Ten R-F Transmission Line Nomographs (continued)

otherwise the phase will vary nonuniformly along the line.

Figure 8 shows the phase relationship of the current at the sending end of a line, with respect to the current in a resistance load, as a function of the ratio of the load resistance to the characteristic impedance of the line, and of the effective length of line. The relationship giving line length in degrees is

$$\phi = \arctan \left[\frac{R_l}{Z_0} \tan \left(360 \frac{l}{\lambda} \right) \right] \quad (8)$$

where R_l is the load resistance, Z_0 is the characteristic impedance and l/λ is the electrical length in wavelengths.

The current in the load will always lag the current at the sending end of a transmission line. It will undergo exactly 180 degrees of phase shift in each electrical halfwave length regardless of the ratio of the load resistance to the characteristic impedance.

9. Voltage Gradient along a Coaxial Line. In a coaxial transmission line the maximum voltage gradient occurs at the surface of the inner conductor. When this gradient exceeds the critical value of approximately 20,000 volts (rms) per cm, breakdown will occur in the form of either corona or arcover. If the characteristic impedance of the line is less than the optimum breakdown value of 60 ohms, arcover will occur without corona; if it is more than 60 ohms, corona will precede arcover.

Figure 9 shows the maximum voltage gradient G_{max} in rms volts per cm on a coaxial line as a function of the characteristic impedance of the line, the physical size of the inner conductor and the applied voltage. The relationship is

$$G_{max} = 47.2E/dZ_0 \quad (9)$$

where E is the applied rms voltage, d is the diameter of the inner conductor in inches, and Z_0 is the characteristic impedance.

FIG. 7
QUARTER WAVE LINE

NOTE—
ADD 90 DEGREES FOR EACH
ADDITIONAL QUARTER WAVE-
LENGTH OF LINE

FIG. 8
PHASE RELATIONS

FIG. 9
VOLTAGE GRADIENT

This nomograph, Fig. 9, is used as follows: first, connect with a straight line points on the first and third scales from the left which represent the inner conductor diameter and the characteristic impedance (see example on nomograph). The intersection of this line with the second scale, labeled Pivot Line, is next connected with a second straight line passing through the desired point on the fourth scale, labeled Applied Volts RMS. The intersection of this second straight line with the fifth scale gives the desired value for the gradient on the surface of the inner conductor in rms volts per cm.

Bead insulators may cause higher gradients in their vicinity, resulting in premature voltage breakdown, particularly if they fit loosely on the inner conductor.

10. *Diminution of Standing-Wave Ratio Due to Line Loss.* A high-frequency transmission line whose characteristic impedance is not matched by the load impedance will have standing waves along its length. The standing-wave ratio in the vicinity of the load will be numerically equal to the ratio of the load resistance to the characteristic impedance (or its reciprocal if this is less than unity). If the line has attenuation, there will be a gradual diminution of the standing-wave ratio in the direction of the generator.

Figure 10 shows the relationship between the standing-wave ratio in a region near the generator (assuming that the wavelength is small compared to the line length), the standing-wave ratio near the load, and the line loss in decibels (as obtained from Fig. 3 and 4). The relationship is

$$db = \left[10 \log_{10} \frac{(S_L + 1)(S_G - 1)}{(S_L - 1)(S_G + 1)} \right]^{1/2} \quad (10)$$

where S_L is the voltage-standing-wave ratio near the load and S_G is the voltage standing wave ratio near the generator.

MIXER HARMONIC CHART

Chart speeds identification or prediction of spurious frequencies resulting from beating of various harmonic terms in mixer output when one input frequency is variable as in wide-band signals for tv, f-m and military communication

IN MANY APPLICATIONS involving the mixing of two frequencies to produce a third, a major difficulty often encountered is the generation of spurious frequencies by beating together of harmonics. When near coincidence with the required terms, these spurious frequencies cause audible modulation of the required frequency that cannot be removed by subsequent selective circuits.

When there are only two fixed frequencies, it is fairly simple to write down all the combination terms involved. If one of the input frequencies varies, however, a graphical method is to be preferred, as this enables the immediate identification or prediction of the various beats and facilitates the choice of frequency ratios free from modulation or spurious frequencies adjacent to the wanted terms.

It was in dealing with such a problem that the accompanying chart was devised. It is based on the fact that the expression for the value of any combination frequency is $F_o = mF_o \pm nF_x$, where m and n are the orders of the harmonics of the two frequency sources F_o and F_x respectively, F_x being the higher of the two frequencies.

To use this chart, trace upward from the ratio F_o/F_x of the two primary frequencies to the two primary frequencies to the heavy difference line $F_x - F_o$ or the heavy sum line $F_x + F_o$, depending on which output component is being used. From this intersection, trace up and down to the nearest slant lines; from each one, trace left to read the F_o/F_x value for that spurious combination frequency. Alternatively, the spurious frequencies can be figured from the identifying notations on the two near-

By **THOMAS T. BROWN**

est lines. Where intersections of two slant lines are nearest to the desired intersection, a beat audio modulation equal to the frequency difference will be produced.

Some problems may require the use of an expanded region of the chart showing higher combination terms. This may readily be constructed to any scale without plotting the whole curve from the origin. Assuming that the boundary limits of the required region are F_{o1}/F_x for the lower frequency limit and F_{o2}/F_x for the upper limit, the corresponding limits on the abscissa are F_{o1}/F_x and F_{o2}/F_x . Now

$$F_o = mF_o \pm nF_x \quad (1)$$

$$F_o/F_x = [(F_o/F_x) \mp n]/m \quad (2)$$

Substituting the four known boundary limits in Eq. 2 gives four equations involving m and n . Substituting for these the harmonic orders of the combination frequencies which it is desired to plot, two points are obtained which are connected by a straight line. This procedure is repeated for the main sum or difference frequency ($m = n = 1$) and other desired pairs.

A preliminary scrutiny of the structure of the general chart will be found helpful in quickly showing what order of combination frequencies are likely to be encountered in the particular region concerned.

Example of Use

In the design of a repeater station for a vhf relay, it is common practice to receive the trans-

mission at a given frequency and retransmit at a slightly higher or lower frequency to reduce feedback difficulties. Rather than convert the input to the output frequency directly, it is convenient to convert down to a lower intermediate frequency, which may then be amplified more easily and reconverted to the output frequency.

Assume an input frequency F_o of 250 mc with a 3-mc bandwidth, and a required output frequency of 240 mc. A convenient intermediate-frequency value for F_i would be in the order of 50 mc. The problem is to choose local oscillator frequencies that will avoid radiation of spurious frequencies and minimize intermodulation distortion.

Trying first 50 mc for F_o , the local oscillator value F_i becomes 200 mc and F_o/F_x for this is 0.8. Tracing upward, this is immediately seen to be a bad choice, because the desired main difference frequency line $F_x - F_o$ intersects both the $4F_o - 3F_x$ and $5F_x - 6F_o$ lines at this point.

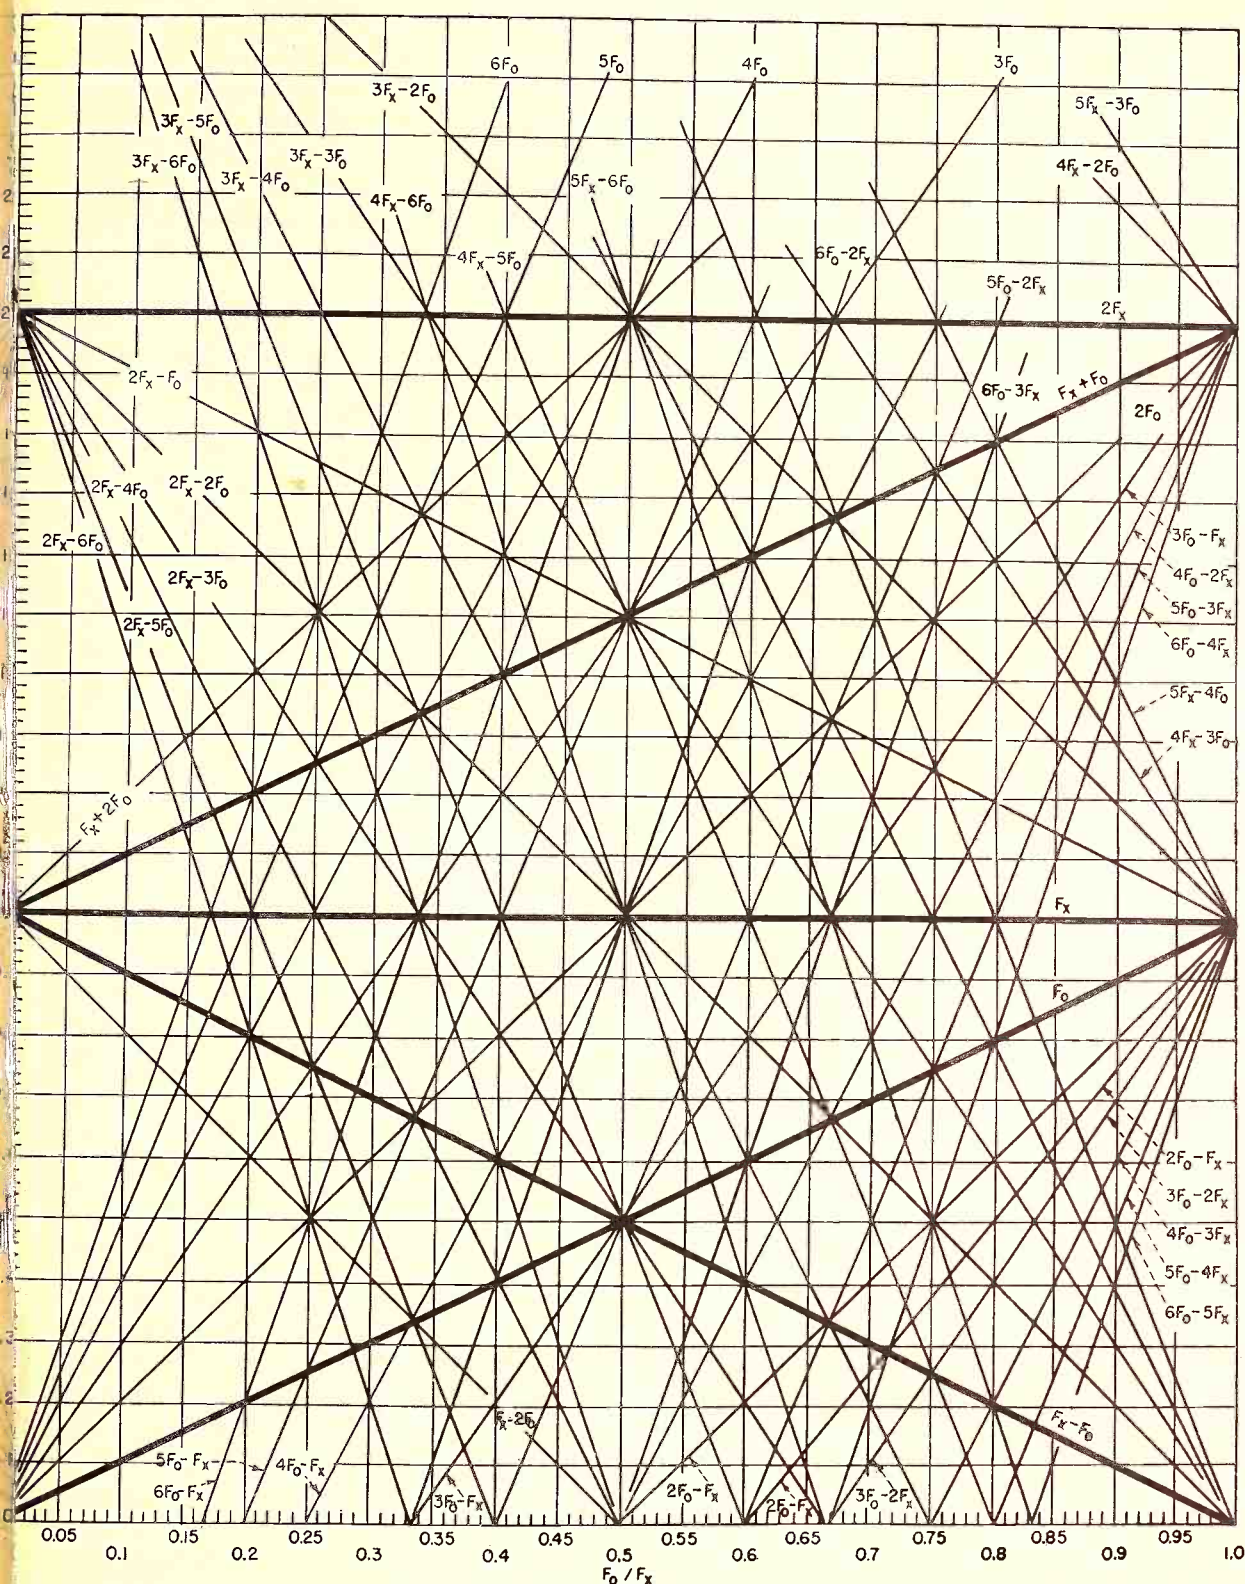

By inspection, the nearest value of F_o/F_x that it is in a clear space on the heavy $F_x - F_o$ line is 0.775, which corresponds to an i-f value of about 55 mc. Tracing vertically up and down from the intersection of the 0.775 ordinate with the $F_x - F_o$ line, we find that the nearest spurious frequencies occur at $F_o/F_x = 0.33$ and 0.12. Their values are quickly figured as $F_o = 0.33 \times 250 = 83.5$ mc and $F_o = 0.12 \times 250 = 30$ mc. If the bandwidth of F_o is 3 mc, these 83.5-mc and 30-mc beats will be easily filtered out of a 55-mc i-f system by the tuned circuits.

Now converting up again, let F_o be 55 mc and let F_i be the

and 240-mc output frequency, so that $F_s = 240 - 55 = 185$ mc, the frequency required of the second local oscillator to get a sum-frequency component. Then F_o/F_s is 0.298. Starting up from this value to

the sum line $F_s + F_o$, the two nearest spurious frequencies to this intersection are at $F_o/F_s = 1.4$ and 1.2. For 1.4, the output is $1.4 \times 185 = 259$ mc due to the combination $2F_s - 2F_o$. For 1.2, we have both $4F_o$ and $3F_s -$

$6F_o$ giving $1.2 \times 185 = 222$ mc. Since the bandwidth is 3 mc, adequate selectivity should not be difficult to provide at 240 mc to discriminate against these 259-mc and 222-mc spurious components.

For chart, with F_o and F_s as mixer input frequencies (with F_s the higher) and F_s as desired output frequency. Lines intersected when tracing straight up from value of F_o/F_s represent combination frequencies, values of which can be read either from labels on lines or from scale of ordinates. Only intersections near desired combination (sum or difference) need be considered. When F_s is fixed, ordinate scale can be marked to give frequency directly

FIELD-POWER CONVERSION

Direct-reading conversion chart enables quick transfer of propagation data from field-strength to power-density values. Gain in db above 1 microvolt per meter and gain or loss in db above 1 microwatt per square meter shows at a glance

IN calculations involving propagation curves it is often convenient to do the computation in terms of power density rather than in terms of field strength, which is given in most propagation curves. Changing field intensity into power density can be greatly simplified by the conversion chart.

The chart is based upon the equation

$$P = \frac{E^2}{120\pi}$$

By **ROBERT E. PERRY**

where E is the field intensity, P is the power density and 120π is the resistance of free space.

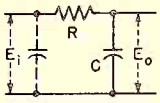

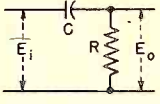

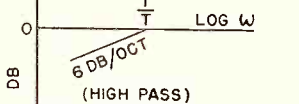

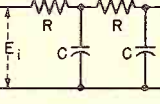

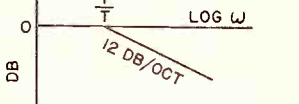

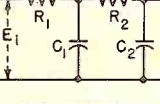

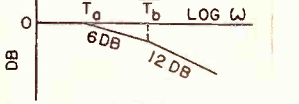

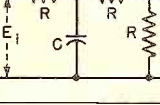

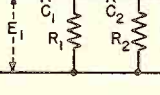

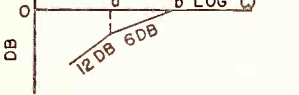

The conversion chart is direct reading. A value on the left scale

can be found in terms of the scale on the right side by reading directly across, or it can be read in terms of the upper or lower scale by reading over to the diagonal line and then up or down to the desired scale.

For example, a field of 500 μv per meter corresponds to a power density of approximately 7×10^{-10} watts per square meter. It is 54 db above 1 μv per meter, or about 32 db below 1 μw per square meter.

Gain curves and ratios of output to input voltage are given for each of thirty different networks. Phase angle equations are included, from which phase response at several representative frequencies is readily computed

THE accompanying tabulation of transfer functions (the ratio of output to input voltage, E_o/E_i) is the result of attempts to determine the electrical equivalent network of a pneumatic servo system and to find a satisfactory equalizer for that system. The phase angle ϕ between E_o and E_i is also given in the tables. Transfer functions of the elementary networks are included for the sake of completeness. Wherever possible the gain curves are represented by asymptotes and the corner frequency which is the intersection of these asymptotes. Where two or more corners exist, they must be of the order of a decade apart in order that the gain curve may

By E. W. TSCHUDI

be represented by asymptotes. When it is desired to compute the actual gain, p should be replaced by $j\omega$ in the transfer function and the amplitude computed in the usual manner for complex quantities, squaring the real and squaring the imaginary components separately, adding and taking the square root. In these expressions $T = RC$. In No. 1,

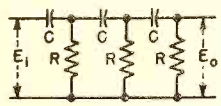

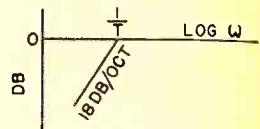

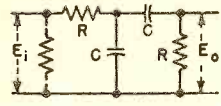

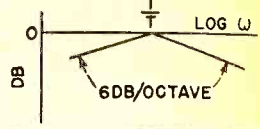

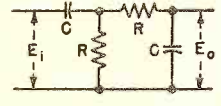

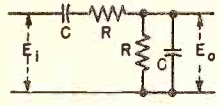

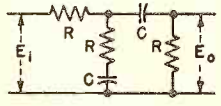

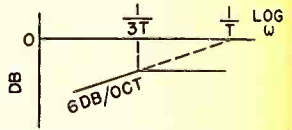

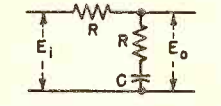

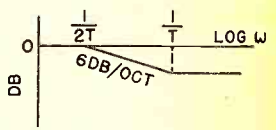

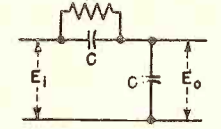

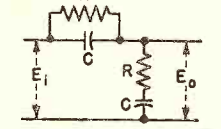

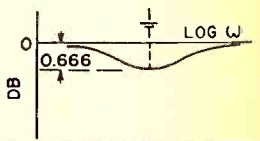

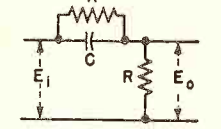

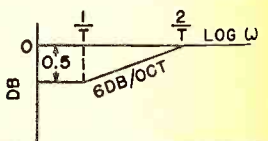

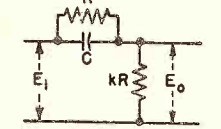

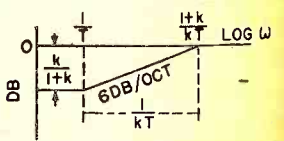

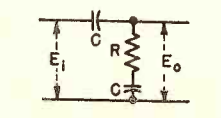

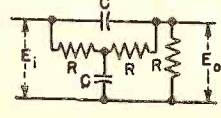

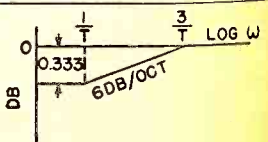

$$A = \sqrt{\frac{1}{1+T^2\omega^2}}$$

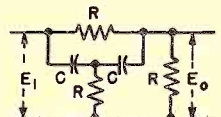

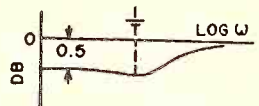

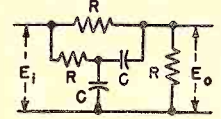

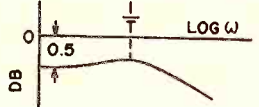

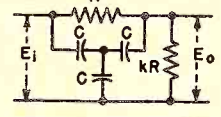

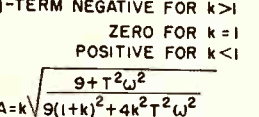

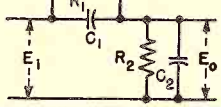

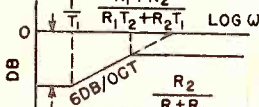

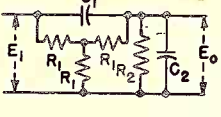

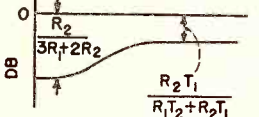

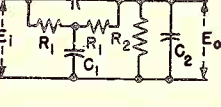

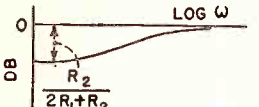

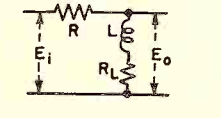

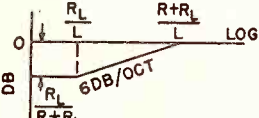

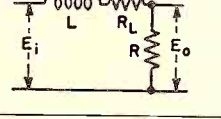

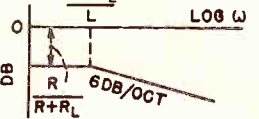

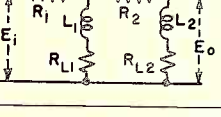

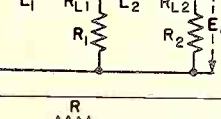

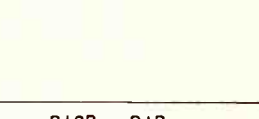

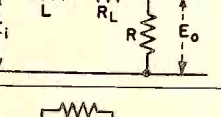

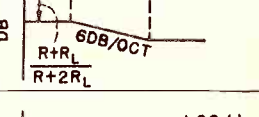

and the gain is $20 \log A$. In networks including inductance, the ohmic resistance of the inductance, R_L , is represented as a practical necessity. Phase re-

sponse curves are not included since it is comparatively simple to compute the phase angle at several representative frequencies. In general the phase angle is positive when the associated gain increases and negative when the gain decreases.

The inclusion of phantom shunt impedances in No. 1 and 8 indicates the transfer functions are not affected by their presence. The values of T_a and T_b in the corner frequencies of No. 4 and 6 are the roots of the quadratic expressions in the denominators of these transfer functions. They are different from the two time constants T_1 and T_2 that are, respectively, R_1C_1 and R_2C_2 . Tables are on following pages.

Transfer Functions for R-C and R-L Equalizer Networks (continued)

CATHODE FOLLOWER RESPONSE

Chart gives permissible cathode-follower pulse drive at video frequencies in terms of low-frequency sinusoidal input. Video-frequency overloading and distortion in conventionally loaded circuits originate in output time constant

By RALPH H. BAER

CATHODE FOLLOWERS frequently overload and distort on video signals when designed on the basis of low-frequency formulas. This behavior results from the effect of the time constant associated with

the output impedance of the cathode follower and the load capacitance. The usual formula for the peak signal permissible is

$$e_{o \text{ peak}} = \frac{E_B}{\mu} \left[\frac{1 + \frac{R_k}{R_p} (\mu + 1)}{\frac{R_k}{R_p} + 2} \right] \quad (1)$$

which is readily calculated. Inspection of Eq. 1 shows that medium values of μ (15-30) are

desirable for maximum permissible input signal.

When a video signal with rise time t microseconds is applied to a cathode follower this permissible grid swing is reduced by a factor of

$$1 + \frac{\frac{R_k}{R_p}}{\frac{R_k}{R_p} + 1} \left(\frac{1 - e^{-\frac{t}{T}}}{\frac{t}{T}} \right) \quad (2)$$

where T is the time constant. Whenever T approaches the pulse rise time in order of magnitude, the reduction in permissible grid signal can no longer be neglected and the correction factor of Eq. 2 becomes essential.

The graph is a solution of Eq. 2; the following procedure applies when a pulse waveform of rise time t is to be handled without distortion where

$$T = \frac{C_T R_k}{1 + g_m R_k}$$

(a) Determine the value of R_k/R_p and t/T . (b) On the graph, connect R_k/R_p with μ . (c) At the intersection of line A with the line drawn in step (b), read vertically up or down to the proper t/T curve. The solution is then obtained from the percent scale by reading horizontally to the left.

As an example, consider a tube with $\mu = 40$, $R_p = 20,000$ and a load impedance of $R_k = 1,000$ and $C_t = 250 \mu\mu\text{f}$ in parallel. From Eq. 1 $e_{o \text{ peak}} = 5.6$ volts for $E_B = 150$ volts. Suppose a video signal with rise time $t = 0.42 \mu\text{sec}$ is handled by the cathode follower. Then $T = 0.0834 \mu\text{sec}$ and $t/T = 5$. From the graph the permissible peak signal is seen to be 72.3 percent of $e_{o \text{ peak}}$ at low frequencies, or 4 volts.

PRODUCT LISTINGS

OF THE 1953-1954

electronics BUYERS' GUIDE

In the preparation of **ELECTRONICS BUYERS' GUIDE**, every effort was made to insure the completeness and accuracy of the Product Listings according to the information provided by the manufacturers.

The listings were compiled from information provided by more than 3,000 companies manufacturing electronic or allied products and include all products that will be available in the coming year, insofar as the companies themselves can determine. The completeness and accuracy of the listings are entirely due to the helpful cooperation of these manufacturers.

Products are arranged and indexed in a simple, easy-to-find, telephone-book style. Names of Manufacturers who are advertisers in the **BUYERS' GUIDE** are bold-faced in the listings and page numbers of their advertisements are shown. This makes it possible to obtain complete information on products quickly and easily by referring to the advertising pages.

Several new product headings have been added. Due to lack of sufficient information, only manufacturers who were known are included under these new headings. Listings include an index of registered trade names and an alphabetical listing of all companies engaged in the manufacture of electronic components, complete equipment or allied products.

NOTE: *This punch-out tab is for your convenience in locating the Product Listings in this issue. Simply push out and fold under. It will then serve as a tab mark to indicate where the listings start.*

Product
Listings

Alphabetical Listings Of All COMPONENTS—COMPLETE UNITS—ALLIED PRODUCTS Used in Electronic Equipment for All Purposes

The complete electronic and allied product lines of more than three thousand manufacturers are arranged and indexed in a simple, easy-to-use, telephone book in the following listings.

Products are listed alphabetically by generic names followed by descriptive or type names where necessary, as **ADAPTERS—Battery**.

For example: To find the manufacturers of ionization tubes you would turn to the generic product heading **TUBES** and listed alphabetically under that you would find **TUBES—Ionization**.

The only exceptions are **INSULATING COMPOUNDS; IONIZATION MATERIALS; INSULATION PARTS; METALS; PLASTIC MATERIALS; and TUBE PARTS**. Products falling in these classifications are arranged alphabetically under their respective headings. A breakdown of electrical measuring

instruments is listed under the generic product heading **INSTRUMENTS, ELECTRICAL MEASURING** and cross-indexed throughout the listings.

Cross references are provided wherever necessary to cover names, other than the standard ones, that are sometimes used.

Manufacturers under each product heading are also arranged alphabetically. Those companies who are advertisers in this issue are bold-faced and the page numbers of their advertisements given to permit quick and easy reference for the necessary technical data.

In compiling the listings for this year's **ELECTRONICS BUYERS' GUIDE** extreme care has been taken to ascertain those products which are in production, or available within a reasonable time and, unrestricted for general industrial use.

THE ONLY *Completely Verified* LISTING OF MANUFACTURERS OF ELECTRONIC AND ALLIED PRODUCTS

RESISTORS

Fixed Composition

1. Low wattage
2. Temperature sensitive
3. High frequency
4. High megohm
5. High voltage
6. High wattage
7. Voltage sensitive
8. Resistor-suppressor

Variable Composition

9. Controls
10. Controls, High Resistance
11. Controls, High Voltage

Wire Wound

12. 2 Watts and under
13. 4 to 35 Watts
14. 4 to 225 Watts
15. 4 to 500 Watts
16. 500 to 1500 Watts
17. Precision low voltage
18. Precision high voltage
19. Rf non-inductive

Variable Wire Wound

20. 4 Watts and under
21. 5 to 25 Watts
22. 25 Watts and over
23. 500 Watts and over
24. Slide wire
25. Adjustable
26. Rheostat—potentiometer types

 Todd-Tran Corp., 156 Gramatan Ave., Mt. Vernon, N. Y.
TRIAD TRANSFORMER MFG. CO., 4055 Redwood Ave., Los Angeles, Calif. ADV. PG. 394.

TRADE NAME INDEX

The following list of trade names of manufacturers and products in or related to the field of electronics has been prepared from data supplied by manufacturers. This list is intended for use in determining the manufacturer's name when only a purported trade name is known. The editors for obvious reasons have not attempted to determine a manufacturer's right to the exclusive use of any such name. Addresses can be obtained by referring to the Manufacturers Index on Page D-169. Only coined trade names are listed, as it was deemed unnecessary to include a company name inasmuch as the manufacturer's identity was immediately apparent.

- A-10**
Surprenant Mfg. Co.
- "A" NICKEL**
International Nickel Co., Inc.
- A BAR E**
Amalgamated Electronics
- ABRASO**
Roebling's Sons Co., John A.
- ABSORB-A-SHOCK**
Federal Shock Mount Corp.
- ACA**
Amplifier Corp. of America
- ACCURAY**
Industrial Nucleonics Corp.
- ACCWIRE**
Accurate Insulated Wire Corp.
- ACE**
American Hard Rubber Co.
- ACE**
Arro Expansion Bolt Co.
- ACME**
Aerovox Corp.

1953-1954 ELECTRONICS BUYERS' GUIDE

MANUFACTURERS INDEX

A listing of the companies engaged in the manufacture of all types of electronic components and complete electronic equipment. They are alphabetically arranged for convenient use and quick reference.

- A B C Radio Laboratories, 3334 N. New Jersey St., Indianapolis 5, Ind.
- A. C. Transformer Corp., 89 Madison St., Newark, N. J.
- 'G/A' Div. of Elastic Stop Nut Corp. of America, 1029 Newark Ave., Elizabeth 3, N. J.
- A J F Industries, Inc., 852 Monroe St., Brooklyn 21, N. Y.
- A. P. W. Co., 72 W. Main St., Rockaway, N. J.
- A. R. F. Products, Inc., 7627 Lake St., River Forest, Ill.
- Abalon Precision Mfg. Corp., 540 Casanova St., Bronx 59, N. Y.
- Accurate Electronics Corp., 1312 Ontario St., Cleveland 13, Ohio.
- Accurate Insulated Wire Corp., 25 Fox St., New Haven, Conn.
- Accurate Mfg. Co., 44 Hepworth Place, Garfield, N. J.
- Accurate Paper Tube Co., 801 N. Peoria St., Chicago 22, Ill.
- Accurate Spring Mfg. Co., 3811 W. Lake St., Chicago, Ill.
- Ace Coil & Electronics Co., 914 Middlesex Ave., Metuchen, N. J.
- Ace Engineering & Machine Co., Inc., 3642 N. Lawrence St., Philadelphia 40, Pa.
- Ace Spring Mfg. Co., 77 W. Houston St., New York 12, N. Y.
- Acheson Colloids Co., 1950 Washington Ave., Port Huron, Mich.
- Ackerman Engravers, 458 Broadway, New York, N. Y.
- Ackerman-Gould Co., 92 Blecker St., New York, N. Y.
- Ackerman-Johnson Co., 625 W. Jackson Blvd., Chicago 6, Ill.
- Acme Battery Co., 59 Pearl St., Brooklyn 1, N. Y.
- Acme Electric Corp., 31 Water St., Cuba, N. Y.
- Acme Electric Heating Co., 1217 Washington St., Boston, Mass.
- Acme Electronics, Inc., 300 N. Lake Ave., Pasadena 4, Calif.
- Acme Electronix Div. of NEA Service, Inc., West Third & Lakeside, Cleveland 13, Ohio.
- Acme Wire Co., New Haven 14, Conn.
- Acro Mfg. Co., 2040 E. Main St., Columbus 16, Ohio.
- Acro-Mu Switch Div., Acro Mfg. Co., Columbus, Ohio.
- Acro Products Co., 369 Shurs Lane, Philadelphia 28, Pa.
- Acro Transformer Mfg. Corp., 26-02 4th St., Astoria 2, N. Y.
- Acromark Company, The, 9-13 Morrell St., Elizabeth 4, N. J.
- Actioncraft Products, 8 Sagamore Hill Drive, Port Washington, N. Y.
- Adams & Westlake Co., Michigan St., Elkhart, Ind.
- Adel Div. of General Metals Corp., 10777 Van Owen St., Burbank, Calif.
- Admiral Corp., 3800 Cortland St., Chicago 47, Ill.
- Advance Electric & Relay Co., 2435 Naomi St., Burbank, Calif.
- Advance Electronics Co., 451 Highland Ave., Passaic, N. J.
- Advance Insulated Wire & Cable Co., Inc., 10 Tingley Lane, Raritown Township, Plainfield, N. J.
- Advance Recording Products Co., 36-12 34th St., Long Island City, N. Y.
- Advanced Electronics, Inc., 94 Silas Deane Highway, Rocky Hill, Conn.
- Aeromotive Equipment Corp., 1632-8 Central St., Kansas City 10, Mo.
- Aerocoil Inc., 24 Cliff St., Jersey City, N. J.
- Aerolite Electronics Corp., 507-26th St., Union City, N. J.
- Aeronautical Communications Equipment, Inc., 3090 Douglas Rd., Miami 33, Fla.
- Aeronautical Electronics Inc., Raleigh-Durham Airport, P. O. Box 6043, Raleigh, N. C.
- Aerovox Corp., 740 Belleville Ave., New Bedford, Mass.

Distributors of **ELECTRONIC COMPONENTS AND EQUIPMENT**

The following is a list of distributors who are selling and stocking, for immediate delivery, electronic components, instruments, audio equipment, associated apparatus and allied products. These distributors perform a valuable service to manufacturers and users by providing quick delivery to meet the urgent requirements of designers and purchasing agents. This list is provided for the convenience of our subscribers and comprises the leading electronic distributors in the United States. Distributors who are advertisers in this issue have their names boldfaced and page number reference made to their advertisements. For further information regarding the services of these distributors, kindly refer to their advertisements.

ALABAMA

Ack Radio Supply Co., 2205 3rd Ave., N. Birmingham 3.
Allen & Jemison Co., Tuscaloosa.
Auto Service Co., 1916 S. 4th Avenue, Birmingham.
Bessemer Radio Supply Co., 116-118 N. 20th, Bessemer.
Clark & Jones, 1601 Second Ave. S., Birmingham.
Clary Co., James W., 1713 Second Ave., Birmingham.
Forbes Distributing Co., 2600 Third Ave., S., Birmingham 5.
Hand Supply Co., 705 S. Oates St., Dothan.
Hand Wholesale Radio, 231 South St., Dothan.
Harris Supply Co., Inc., 10 N. Water St., Mobile 6.
McDavid & Co., Inc., R. P. 1430 Second Ave., Birmingham.
McGowin-Lyons Hardware & Supply Co., 113-125 N. Water St., P. O. Box 1209, Mobile.
MG Electrical Equipment Co., 203 S. 18th St., Birmingham 3.
Nelson Radio & Supply Co., 263 St. Louis St., Mobile 10.
Nolin-McInnis, Inc., 205 Commerce St., Montgomery 3.
Radio Distributing Co., 1724-5th Ave., Birmingham 3.
Radio Distributing & Supply Co., 1029 Guinee St., Anniston.
Reid Distributing Co., 1724 Fifth Ave., N., Birmingham.
Signal Radio Supply Co., 243 E. Troy St., Dothan.
Southeastern Radio Parts Co., 120 Chestnut St., Gadsden.
Southeastern Radio Parts Co., 210 Court St., Montgomery.
Steel City Supply Co., 600 N. 7th St., Birmingham.
Teague Hardware Co., 132-134 Commerce St., Montgomery.
Walther Bros Co., 113 Commerce St., Montgomery.

ALASKA

Alaska Radio Supply Co., Inc., Box 2165, Juneau.
Alaska Radio Supply, Inc., Box 84-318 8th Ave., Anchorage.
Yukon Radio Supply, Box 406 Anchorage.
Yukon Radio Supply, Box 1385, Fairbanks.

ARIZONA

Dalis Brothers, 528 E. Pierce, Phoenix.
Electrical Equipment Co. of Arizona, P. O. Box 2630, Phoenix.
Elliott Laboratories, 418 N. 4th Ave., Tucson.
Midland Specialty Co., 233 S. 11th Avenue, Phoenix.
Radio Parts of Arizona, 214 S. 11th Ave., Phoenix.
Radio Specialties & Appl. Corp., 305 E. Roosevelt, Phoenix.
Ra-Tone Electronics Co., 128 W. Washington, Phoenix.
Southwest Wholesale Radio & Appliance Co., 126 S. Second St., Phoenix.
Standard Radio Parts, 218 North First Ave., Tucson.
Western Radio Engineering Co., 1915 E. Washington St., Phoenix.

ARKANSAS

Blytheville Radio Supply, 112 S. First St., Blytheville.
Carlton Wholesale Radio, Inc., 109 W. 9th St., Little Rock.
Carter Electronic Supply Co., 805 N. 11th St., Fort Smith.
Interstate Electric Co. of Shreveport, Inc., Fort Smith.
Interstate Electric Co., of Shreveport, Inc., Texarkana.
Lavender Radio Supply Co., 522 E. Fourth St., Texarkana.
Martin Wholesale Radio Supply, 1207 W. Kingshighway, Paragould.
Southern Radio Supply, 1419 Main St., Little Rock.
Thurman Supply Co., 115 W. 11th St., Little Rock.
White Radio Supply Co., David, P. O. Box 408, 1224 Main St., Little Rock.
Wise Radio Supply, 1001 Towson Ave., Fort Smith.

CALIFORNIA

Altshuler Co., Cass, 6038 Telegraph Ave., Oakland.

Applied Electronics Co., Inc., 1246 Folsom St., San Francisco.
Arbuckle, Jack C., 417 E. 19th Street, Bakersfield.
Arbuckle, Jack C., 2330 Kern St., Fresno.
Associated Radio Distributors, 1251-3 Folsom St., San Francisco.
Barrett, Kaemper, Dealers Supply Co., 1850 Mission St., San Francisco.
Braun Corp., 2260 E. 15th St., Los Angeles 21.
Braun-Knecht-Heimann Co., 1400 16th St., San Francisco.
Brill & Co., W. D., 198 10th St., Oakland.
Brill Co., W. D., 96 Camino Encinas, Orinda.
Brown Co., C. C., 1714 Tenth St., Sacramento.
Brown Co., C. C., 61 Ninth St., San Francisco 3.
California Electronics Supply, 11801 W. Pico Blvd., Los Angeles 34.
Capitol Records, Inc., Sunset & Vine, Hollywood 28.
Channel Radio Supply Co., 523 Anacapata, Santa Barbara.
Coast Electric Co., 744 G St., San Diego 12.
Coast Electronic Supply Co., 527 W. Main St., Alhambra.
Commercial Electronics, 317 W. 7th St., Eureka.

Electron Tubes

"ACROSS THE BOARD"

—for industry and the armed forces

RCA offers you a comprehensive line of quality-engineered tubes—designed to fill the exacting requirements of a wide range of industrial and defense applications. Look to RCA as a dependable source for your tube needs.

RCA will be glad to help you select the right tube type for your design requirements. For this help—and for technical information on specific tube types

—write RCA, Commercial Engineering, Section 43R, Harrison, N. J. Or simply get in touch with the RCA field engineers at your nearest field office:

(EAST) Humboldt 5-3900

RCA TUBE DEPARTMENT

How these "spheres" of RCA Engineering —work for YOU

RCA Development and Design Engineering—anticipates the need for new electron devices, and translates your requirements into practical designs.

RCA Quality Control Engineering—assures consistent quality, from the raw materials to the finished product.

RCA Production Engineering—develops production techniques and maintains product reliability.

RCA Commercial Engineering—edits and publishes the industry's most useful and comprehensive technical publications, for your convenience in using RCA Tube Department Products.

RCA Application Engineering—solves your special problems in tube and component applications.

RCA Field Engineering—provides "on-the-spot" technical consultation service—co-ordinates your require-

ments with other RCA Tube Department Engineering Services.

For expert help from your RCA Field Engineer, write RCA Commercial Engineering, Section 43R, Harrison, N. J. Or contact your nearest RCA Field Office:

(EAST) Humboldt 5-3900
415 S. 5th St., Harrison, N. J.

(MIDWEST) Whitehall 4-2900
