COMPLETE COLOR TV SIGNAL GENERATING and TEST EQUIPMENT

for the **BROADCASTER • LABORATORY • MANUFACTURER**

From the Wickes electronics laboratories, every type of equipment required to generate a color signal . . . every unit you need to accurately test and control color signal quality.

VECTOR DISPLAY EQUIPMENT—Model VDE-3A

The only "packaged" vector display unit complete with Oscilloscope—furnished rack-mounted with cable connections, ready for immediate installation. Equipment consists of Display Oscilloscope, Decoder and Keyer, Burst-Controlled Oscillator, and Regulated Power Supply. Individual units also available separately.

COLOR BAR GENERATORS—
6-Channel and 7-Channel Models

COLOR CODER—Model CC-2

CONVERGENCE DOT GENERATOR—
Model CDG-1

VIDEO DISTRIBUTION AMPLIFIERS—
1, 3 and 5 Channel Models

MULTI-BURST GENERATOR—Model MBG-1

AMPLITUDE LINEARITY TESTER—Model ALT-2

PULSE DISTRIBUTION AMPLIFIER—
Model PDA-2—6 outputs

ALL EQUIPMENT ABOVE COMPLETE WITH SELF-CONTAINED FILAMENT SUPPLY

REGULATED POWER SUPPLIES—300 MA., 400 MA., and 600 MA. Models

ENVELOPE DELAY TRACER—Model EDT

COLOR VIDEO MONITOR—Model CVM-1

Portable, self-contained monitor designed to check picture quality of standard F.C.C. (N.T.S.C.) color signals or monochrome signals.

PHASE CORRECTION NETWORKS—
HF Fixed and Adjustable Models

CROSSOVER FILTER—
Model COF-1, portable or rack-mounted

COLOR PHASE ANALYZER—Model CPA-1

BEFORE YOU INVEST IN COLOR TV EQUIPMENT investigate these units from Wickes. Complete engineering service is included with all equipment. Detailed data and prices on listed equipment are available upon request . . . or write for complete Wickes catalogue.

NEW . . . FOR DESIGNERS . . . PHASE DIS- PLAY EQUIPMENT—Model PDE-1

Ideal for transistor studies and testing, Wickes Phase Display Equipment provides unusual speed for simultaneous vector plot of amplitude and phase, distortion measurement, displays the transfer function of any network, amplifier or system. Supplied complete with cabinet, interconnecting cables and full instructions.

**1500 WATT HOMELITE
GENERATOR**

Model 35A115
Homelite Generator
1500 Watts, 115 Volt
60 Cycle AC
90 Pounds

- 1. New Money-Saving features...** No DC brushes; just two easy-to-get-at collector ring brushes... No commutator or DC windings... No intermediate couplings; armature keys directly to shaft. Fewer parts to wear out — longer trouble-free generator service.
- 2. Constant Voltage...** less than 4% change from no load to full 1500 watt capacity... assures long service life for your electrical requirements... guarantees top performance at all times.
- 3. Overload Capacity...** 1500 watt continuous duty with generous overload capacity prevents stalling under heavy loads... insures uninterrupted service even when starting loads exceed operating loads.
- 4. Compact and Lightweight...** one man can easily carry this generator wherever you need electricity to power time-saving electronic and communications equipment. No need for long, hazardous power-consuming cables.

SAVE EVEN MORE!

New Homelite idle control unit, available as optional accessory, runs engine at idle speed when no current is drawn... automatically brings engine to full speed when load is applied.

THE MOSELEY
AUTOGRAF
trade mark
X - Y RECORDER

Three versatile models feature ranges from 5 millivolts to 500 volts; 200,000 ohms per volt input resistance; zero set and full scale zero off-set; speeds up to 1/2 second full scale; accuracy of 0.25%.

Rugged and stable, all models provide facilities for curve drawing and curve following. Digital data may be plotted in point form from keyboard, tape, or card sources, utilizing accessories described below.

MODEL 1
Drum type
8 1/2" x 11" paper
X-Y Recorder-
Curve Follower

MODEL 2
Flat-bed
11" x 16 1/2" paper
X-Y Recorder-
Curve Follower-
Point Plotter

MODEL 3
Desk Type
8 1/2" x 11" paper
X-Y Recorder-
Curve Follower

MOSELEY ACCESSORY PRODUCTS

MODEL 40 KEYBOARD provides a convenient means for plotting large amounts of tabular data in point-curve form. Self-contained voltage source together with full three column keyboard in both X and Y axes; unit plugs directly into MODEL 2 AUTOGRAF.

MODEL 20 DC VOLTMETER is a servo-actuated, fast, accurate and sensitive instrument. Has large, easy-to-read scale for general laboratory use where ranges from 3 millivolts to 300 volts are desired. For data handling it is furnished with a built-in Coleman digitizer and delivers digital output for operation of printers, typewriters, tape or card punches, etc.

MODEL 30 CARD TRANSLATOR converts information from punched cards into point form for automatic plotting. Handles up to 50 cards per minute, 10 to 200 counts per inch. Plugs directly into MODEL 2 recorder, controls both card reader and recorder for completely automatic operation.

Bulletins describing these instruments are available and we'll be glad to send them to you.

Precision Gearing

- ★ WORMS
- ★ RACKS
- ★ SPUR GEARS
- ★ SPIRAL GEARS
- ★ WORM GEARS
- ★ HELICAL GEARS

We specialize in the manufacturing of fine pitch gears of the types widely used in the electronics and instrumentation fields, cut to the close tolerances demanded by modern advanced engineering. We are equipped to produce these items either complete or on a "cutting only" basis, in pitches as fine as 200, from the minute sizes up to 8" dia. Meticulous testing procedures and equipment are used for precision quality control, and we will furnish Fellow's Red Liner Charts with finished gears on request, offering graphic proof of our accuracy.

TEFLON[®]
SNAP-LOCK terminals

- new principle (patent pending) eliminates terminal boards
- terminals install directly in chassis
- provides ground ring for sensitive circuits

Lerco's new Teflon insulated terminals make possible new design methods which eliminate terminal boards. The terminals, individually insulated from the metal by Teflon, may be installed directly in the chassis. First, the Teflon sleeve is snapped through a hole in the chassis. Then the terminal is inserted and swaged over the insulator to lock the assembly solidly in place. Lerco Teflon insulated terminals will withstand severe shock and vibration conditions.

The Lerco terminals (patent pending) are now produced in sizes for .035, .050, and .062 thickness material. Illustrated above is Number 4075. For other variations now available and for further information, write for complete brochure.

TELEX

...leader in
miniaturized
components

AT Telex, design and development of precision miniaturized component parts is a continuing effort. Ever increasing demands for smaller, lighter components operating within close tolerances have created a proved line of miniature parts—all ready for application to your immediate problem!

These demands too, have created a backlog of engineering experience—"know-how" that will meet your "special design" problems efficiently and at surprisingly low development cost! Write today for information about Telex—its complete facilities and its service program.

1 MIDGET TRANSISTOR TRANSFORMERS

... for transistorized circuitry: audio amplifiers, hearing instruments, control circuits.

2 SUB-MINIATURE JACK AND PLUG COMBINATION

Closed circuit jack and plug combination, 1/3 size of conventional models.

3 BOOM-TYPE HEADSET

... rugged, lightweight unit for pilots, receptionists and other two-way headset users.

4 DECADE RESISTOR ...

... for dependable accuracy in electronic computers. Miniaturized.

5 ENCAPSULATED ASSEMBLIES

... protect electronic assemblies from vibration and atmospheric conditions.

6 MINI-MIKE ...

... rugged miniature speaker-microphone with high sensitivity, good frequency response.

precision, seamless

DEEP-DRAWN CASES

at low cost

...even on short runs

Zero uses a unique, super-depth drawing method which permits low cost tooling and fewer operations. These economies result in high-precision drawn cases and chassis at competitive prices.

Special precision presses hold close tolerances with sidewalls of uniform thickness and no draft. No intermediate heat treatments needed. Cases are satin-smooth, due to the use of specially compounded lubricants.

STOCK CASES

Choose from over 1200 standard stock sizes and save tooling costs! You get seamless, high-precision deep-drawn cases on one-week delivery. All items can be modified by secondary operations...holes punched, fasteners installed, etc. Wide assortment of rectangular, round and square boxes and covers. Send for catalog.

CUSTOM DEEP-DRAWING

Zero cuts costs on specials by exclusive technique for producing low-cost dies. The use of special presses results in extreme precision, quality and economy in custom deep-drawing. Even in relatively small quantities prices, including tooling costs, are competitive with fabricated cases.

INSTRUMENT CASES

This handsome deep-drawn aluminum case is a stock model...one of 6 basic sizes, all available promptly in any quantity. Recessed front cover protects knobs and dials...gracefully styled. Cases and covers can be modified to your specifications and furnished complete.

MIL-W Specification CARRYING CASES

Extra-rugged cases are deep-drawn of aluminum for high strength and precision. Special extruded gasket retainer provides positive seal. Cases are built to exceed the requirements of MIL-W specifications. Many standard sizes available eliminate draw tooling costs.

Send for complete Zero catalog, indicating your individual requirements.

ELECTRONIC DESIGNERS GO FIRST TO THE "GUIDE"

Wherever designers and specifiers have immediate need for readily accessible, necessary product information at their breadboards, there, year after year, will you find the ELECTRONICS BUYERS' GUIDE. "Who makes what product or provides what service?" "Where can I buy it?" "Where can I find complete and accurate product specs?" These are questions that are asked daily by the men who design-in electronic products; these are questions that have been answered for the past fifteen years by the "Guide," the accepted reference book of the industry.

Year after year, the designers of the industry have preferred the "Guide" for its *Simplicity of Style* (as easy to use as a telephone directory), for its *Accuracy* (the industry helps the Research Staff revise its listings every year) and its *Complete Product Specs* (advertisers have told their complete product stories in the "Guide" consistently).

The key people of the industry — the buying influences—rely on the "Guide" for the answers to their product problems.

CO-AXIAL SWITCHES, MICROWAVE TEST EQUIPMENT and PRIMARY POWER STANDARDS

PULSE POWER CALIBRATOR

MODEL PCX-1 PULSE POWER CALIBRATOR is an extremely precise instrument for calibrating pulse power measuring devices in the 925- to 1225-mc frequency range and for measuring power between -10 and +63 dbm to within 0.5 db. It is the first in a series which includes similar calibrators designed for the 3000-mc, 5000-mc and 9000-mc bands. This equipment employs a new method which permits far greater accuracy (other than calorimetric) than heretofore achieved. It establishes a measurement reference level at the time of each use. Ease of operation is assured by the notch-and-reference-line display, by the automatic centering of pulses on the display, and by the direct reading of power measurements. The removable bisectonal cover, frame construction, hinged and pivoted subchassis assure easy accessibility for servicing.

MINIATURIZED SWITCHES

A new line of inexpensive, miniature, light-weight, versatile co-axial switches.

GENERAL CHARACTERISTICS

Frequency Range: 0 to 10,750 mc/s. VSWR: 1.25 at 3000 mc/s - 1.5 at 10,750 mc/s. Insertion Loss: 0.25 db up to 9000 mc/s. RF Power Rating: 100 watts average - 1500 watts peak. Voltage Rating: 500 volts peak. Crosstalk: greater than 70 db up to 9000 mc/s. Impedance: 52 ohms nominal. Actuator Voltage: 28 volts DC nominal. Actuator Power: 10 watts average continuous. Operative Life: 100,000 cycles. Operating Temperature: -55°C to +85°C. Connector Type: N, BNC, or C. Weight: 10 ounces. Dimensions: 2.5 in. x 2.875 in. x 0.875 in. Switching Arrangement: SPDT. Mounting Features: Mounts flat against panel, chassis or frame; multiple-stacked compactly.

MANUAL CONTROL SWITCHES

Compact, lightweight - available in Radial; parallel connector configuration.

GENERAL CHARACTERISTICS

Frequency Range: 0 to 10,500 MC. VSWR: 1.2:1 max. at 3000 MC. Insertion Loss: 0.3 db max. Crosstalk: greater than 60 db at 3000 MC, greater than 40 db at 10,500 MC. Operation Life: 10,000 cycles, min. Construction: weatherproof. Connectors: N, BNC, C, HN, BN, LN. Positions: 2, 3, 4 and 6: single and double pole. Easily adaptable for specialized usage.

REMOTE CONTROL SWITCHES

28 V. DC., 110 V. DC. - Compact, lightweight - available in Radial, spring return; Radial, transfer; parallel connector configuration. 115 V. AC., 60 cycle. - Compact, lightweight - available in Radial, spring return; parallel connector configuration.

GENERAL CHARACTERISTICS - See Above

"S" BAND BEACON

A highly miniaturized receiver-transmitter for missile applications to facilitate radar tracking. Supplied with power supply, cable and antenna (not shown).

"X" BAND TEST EQUIPMENT

TEST SET BHS (AN/UPM-10A)

A portable microwave signal generator for testing and adjusting beacon equipment and radar systems operating in the range of 8500 to 9600 MC. Measures power and frequency of external signals. Supplies pulse-modulated, square-wave-modulated or unmodulated signals of known power and frequency. Also supplies frequency-modulated signals.

NEW! MODEL BDX FOR GREATER ACCURACY

Greater frequency accuracy (± 1 mc from 8500 to 9600 mc). Greater power level accuracy (± 1.5 dbm without correction curves). Repetition rates high enough to measure recovery time with assurance (up to 50,000 PPS). Operates with or without an auxiliary trigger. More rugged and dependable. The only complete signal tester for beacon work.

Manufacturers with products to sell in the Field of Nuclear Energy find that advertising in NUCLEONICS is a sure-fire method of moving those products because they reach 11,000 potential purchasers through the advertising pages of NUCLEONICS. From Absorbent Paper to Zinc Bromide... products in the Field of Nuclear Energy are SOUGHT and BOUGHT by important Physicists, Metallurgists, Geologists, Biologists, Physicians, Radiologists, Bio-Chemists, Engineers, Technicians and Management because these important buying influences go first to the sales pages of NUCLEONICS for product data in Nuclear Energy.

Get TEFLON[®] that behaves as it should

Did you know that Teflon comes in various "grades"? Grade is governed by processing method and by purity. When you get the right grade for the job you will benefit by consistent performance from Teflon.

Premium grade is derived from virgin Teflon. That's what you get with "electrical grade" Fluoroflex-T. Conformance to important properties is *certified*.* Its non porosity and optimum tensile strength assure reliability in even the most exacting service.

Economy is achieved without impairing chemical inertness in "mechanical grade" Fluoroflex-T. Some physical features of this reprocessed Teflon are even improved, since it offers better resistance to elongation with better dimensional stability the result.

In addition, *uniformity* of both grades is assured by exacting quality control standards and by relieving of internal stresses in Fluoroflex-T rods, sheets, tubes and parts.

Send for more data—and for quotations on your needs.

*Copies of test reports on file available on request.

©Fluoroflex is a Resistoflex registered trade mark for products from fluorocarbon resins. Teflon is the DuPont registered trade mark for its tetrafluoroethylene resin.

MYLAR* Available in 4 Types:

Miniature Metal Tubular; Molded;
Uncased; Bakelite Encased.
Voltage Ranges — 100 to 600 vdc.

Applications re-
quire small size, and
high insulation re-
sistance to 125°C.

POLYSTYRENE Available in 8 Types:

Miniature Metal Tubular; Molded; Un-
cased; Bakelite Encased; Glass Encap-
sulated; Bathtub can types (fixed and
variable capacitance) and CP-70 type
cans.
Voltage Ranges — 100 to 600 vdc.

High stability,
imperviousness to
moisture, low di-
electric absorption
and high insulation
resistance are
requisites.

TEFLON Available in 3 Types:

Glass Encapsulated; Metal Tubular and
CP-70 type cans.
Voltage Ranges — 200, 400 and 600
vdc with 1,000 vdc upon request.

Applications at
170°C and 200°C.
Where size is a
problem.

POLYETHYLENE Available in 2 Types:

Glass Encapsulated and CP-70 cans.
Voltage Ranges — 100 to 600 vdc.

Pulse and RF appli-
cations at low tem-
peratures.

CELLULOSE ACETATE Available in 2 Types:

Glass Encapsulated; CP-70 Style Cans.
Voltage Ranges — 600 to 40,000 vdc,
with up to 100,000 vdc upon request.

High voltage appli-
cations where small
size is demanded.

*MYLAR, Dupont Trade Name for Polyethylene Terephthalate.

WIDE RANGE SPECTRUM ANALYZER

Model SS-100

SPECTRUM ANALYZERS

MODEL SS-5	1 cycle to 5 KC	Resolution to 2 cycles.
MODEL SS-100	13.5 cycles to 110 KC	Resolution to 27 cycles.
MODEL SS-500	5 KC to 500 KC	Resolution to 150 cycles.
MODEL UR-10	100 KC to 10 MC	Resolution to 500 cycles.

Model MO-7

MINIATURE and MULTIPLE CHANNEL OSCILLOSCOPES

Automatic Tracking Spectrum Analyzers . . . Auto-
matic Phase Plotters . . . Synchronous Sweep Gener-
ators . . . Calibrated Noise Sources . . . Probe
Oscilloscope . . . 0 to 100 KC Calibrator.

PROBESCOPE CO.

RELAYS and CONTROLS

SUB-MINIATURE RELAY

(Series 500)

Withstands greater shock and vibration than any other Sub-Miniature Relay. Available with 2, 4 or 6 PDT contacts, rated at 2 amperes, 26.5 VDC non-inductive. Standard coil voltage 26.5 VC available for Class A, B or C service of Spec. MIL-R-5757. For DC operation only.

MIDGET RELAY

(Series 1000)

An exceptionally small and compact relay, weighing slightly over 1 ounce. Contacts SPDT, rated 1 ampere 50 VDC, non-inductive. DC voltage range: 3 to 24.

HERMETICALLY SEALED RELAYS

Husky sealed relays operate under ideal conditions at all times, regardless of the surrounding atmosphere. . . . Specified repeatedly for military and industrial use. Standard DC voltages only.

MULTIPOLE RELAY

(Series 2100)

A versatile relay designed for military and commercial needs. Two frame sizes are available, providing up to 6 PDT contacts, rated as high as 15 amperes, 24 VDC non-inductive. DC relays are available with single or double coils for voltages up to 120. AC relays available up to 250V, 50 to 60 cycle.

ROTARY RELAY

(Series 8000)

A compact, powerful and efficient, rotary-driving mechanism. Practically immune to shock and vibration. Operates standard wafer switches. DC operation only.

COAXIAL RELAYS

(Style 6393)

Style 6393 with 3 BNC fittings is only one of many styles of coaxial relays available. The relay shown is available for DC operation only. Other styles available for either AC or DC operation.

AIRCRAFT TYPE RELAY

(Type 5002-A)

The 5002-A relay, supplied for aircraft use, meets requirements of drawing AN3320-1. Standard unit available for 26.5 VDC operation.

TIME DELAY RELAYS

Synchronous motor type, with either 2 or 3 snap-action switches available. For timing application requiring a delay period of 15 seconds to 15 minutes at fixed time intervals. This series available in various styles and contact combinations.

PRICE ELECTRIC

Corporation

5300 CHURCH ST.
Frederick, Maryland

MINIATURE INDICATOR LIGHTS BY ELDEMA

E-Lites—designed for military and commercial applications. Small size—most types only 3/8 inch diameter. Light-weight aluminum construction. Plastic lenses in various colors. Neon lamps are NE-2A. Incandescent lamps are T-1-3/4 in 6, 12, and 24 volts. **1A** E-Lite #1A. Neon—internal resistor is optional. **1B** E-Lite #1B. For snap-in mounting, replaces grommet-mounted NE-2. **1D** E-Lite #1D. With replaceable plug-in neon lamp. **1E** E-Lite #1E. Neon—for data read-out applications. Internal resistor is optional. Digits, letters or other special markings available on lens face. **1F** E-Lite #1F. Dual lamp indicator with replaceable plug-in neon or incandescent lamps and optional color combinations. **1G** E-Lite #1G. Incandescent with flush lens. Available with special markings on lens face.

SPECIFICATIONS

- All units are hermetically sealed
- Winding forms and strip material are made of the same synthetic thermo-setting compound
- Maximum resistance is based on use of .0009 inch dia. 800 OHM/C.M.F. wire
- Tolerances of $\pm 1\%$ are available in resistance values down to 1000 OHMS
- Standard windings are non inductive
- Ambient operating temperature range -65°C to $+125^{\circ} \text{C}$
- Multi-strip units may be provided with additional material on each end for mounting

PRINTED CIRCUIT TOROIDS

**bolt them down
and forget them!**

- Low level transformers • 400 cps to 10 kc power transformers • Lo-hi band-pass filters • Magnetic amplifiers • Saturable reactors • Switching transistor power supplies

featuring:

- Hard glass sealed headers • Vacuum impregnation • Class "H" insulation types • MIL-T-27 construction • Absolute minimum size and weight • Large variety of sizes

Send us your specs. We will forward literature on a standard unit, or submit a bid which includes design. Deliveries average 2 weeks on prototypes.

ARNOLD MAGNETICS CO.

5962 Smiley Drive, Culver City, California

ARNOLD TOROIDAL COIL WINDER

*sets up quickly... easy to operate...
takes wide range of wire sizes*

SPECIFICATIONS:

- Min. finished hole size: .18 in.
- Max. finished toroid O.D.: 4.0 in.
- Winding speed: 1500 turns/min.
- Wire range: AWG 44 to AWG 26
- Dual, self-checking turns counting system
- Loading (wire length) counter
- Core range: 1/4" I.D. to 4" O.D. to 1 1/2" high

LABORATORY USE

- Change wire and core size in 45 sec.

PRODUCTION USE

- 1500 turns per minute
- Insert core and load in 20 sec.

PORTLAND, OREGON

General purpose C-R-L imped-
ance and comparison bridges
and accessories; high accur-
acy rheostats and potenti-
ometers; decade resistance
and capacitance units.

GERTSCH PRODUCTS, INC.
LOS ANGELES, CALIFORNIA

High accuracy VHF-UHF fre-
quency meters; supersonic,
audio, and sub-audio filters;
precision variable ratio
transformers; complex volt-
age ratio bridge; and peak
reading VTVM.

HEWLETT-PACKARD CO.

PALO ALTO, CALIFORNIA
Signal generators, frequency
counters, oscillators, volt-
meters, oscilloscopes, and
associated laboratory test
equipment up to 40,000
megacycles.

KAY LAB
SAN DIEGO, CALIFORNIA

Highly regulated DC power
supplies; microvolt level DC
amplifiers and VTVM's; indus-
trial and broadcast TV
camera and monitor systems.

SANBORN COMPANY
CAMBRIDGE, MASSACHUSETTS

Oscillographic recorders in
single and multiple channel
systems, employing plug-in
preamplifiers for maximum
versatility.

SENSITIVE RESEARCH INSTRUMENT CORP.
NEW ROCHELLE, N.Y.

High accuracy ammeters,
voltmeters, wattmeters, flux-
meters, special purpose
meters, and universal test
sets in a wide selection of
types and ranges.

SIERRA ELECTRONIC CORP.
SAN CARLOS, CALIFORNIA

Instrumentation for carrier
current communication, line
fault analyzers, and VHF-UHF
communication test equip-
ment.

VARIAN ASSOCIATES

PALO ALTO, CALIFORNIA
Klystrons and advanced
microwave tubes, research
electro-magnets, strip chart
recorders, and accessory
items.

we love new challenges!

Whether you have dragons or tough instrumentation problems on hand, we're well armored to help you overcome them! Our round table staff of seven highly trained sales engineers is armed with the latest in electronic equipment and its applications. And our service department stands ready to maintain that equipment in fighting condition at a moment's notice.

If you would like to receive "Instrument Notes" monthly, drop us a line. We cover Eastern Pa. and Southern N. J.

Representing the following widely recognized product lines

Jsh

SALES CO.

SPECIALISTS IN ELECTRONIC TUBES

FOR INDUSTRY, COMMUNICATIONS, RESEARCH & EXPORT

JSH 6 Star Program of Quality, Value & Service

- ★ IMMEDIATE DELIVERY on most tubes from one of the largest inventories in the U. S. (over 2000 types)
- ★ HARD TO GET—Klystrons, Magnetrons, Thyratrons, Ignitrons, TR, rocket and newer type Transistors, Miniature, & Sub-Miniature tubes.
- ★ NAME BRANDS—General Electric, RCA, Raytheon, Sylvania, Tung Sol, Western Electric etc.
- ★ UNCONDITIONAL GUARANTEE—Backed by certified testing facilities (testing to Jan. MIL-E-1B or other specifications if desired)
- ★ LOW PRICES—consistent with top quality
- ★ FAST SERVICE—on quotations, inquiries, deliveries

TUBES

Receiving, Transmitting, Special Purpose, Cathode Ray, Crystal Diodes

this Searchlight Section of ELECTRONICS

is an index of reliable sources for Used and Surplus Equipment now available. Consult the **Searchlight Section** in regular monthly issues for later offerings.

If you don't see what you want—ask for it. Ask the advertisers. They are constantly adding to their stocks and may have acquired just what you need. Or, shall we ask them for you—see Equipment Spotting Service page 716.

And, when you have special items to dispose of, use the Searchlight Section of Electronics to help you locate buyers. . . . Send a list of your equipment and we will gladly give full information as to space and rates.

COMPASS ELECTRONICS SUPPLY

A Division of Compass Communications Corporation

WE MAINTAIN OUR OWN FULLY EQUIPPED TESTING LABORATORY TO TEST AND GUARANTEE ANYTHING WE SELL

Wholesale, Industrial and Institutional Sales Only

75 Varick St., N. Y. 13, N. Y.

Canal 6-7455

Cable: Compradio, N. Y.

COMPASS—has approximately 100,000 square feet of warehouse space filled with carefully selected electronic equipment and parts. All of it is sold to users with full guarantee—you may buy with full confidence at COMPASS . . . In this advertisement only a general indication of our stock is given—with a little emphasis on test equipment, microwave accessories and rotating machinery. If you don't see what you want please write for it.

SA-2 RADAR

Used for air traffic control, tracking and search, both land-based and ship-borne, 5 microsec. pulse, PPI indication, operates at 200 mcs, peak power of 150 K.W. Input 110/120 volts a.c. 4 complete installations in stock.—Write for price.

APS-3—3 cm—Airborne radar for search and homing, 5-in. scope. 10 brand new sets at. \$495.00 ea.

APS-4—3 cm. airborne radar, complete. \$495.00

APS-15—3 cm. airborne radar, complete. Write

APS-20—3 cm. airborne radar, complete. \$2,950.00

APQ-13—Very late model airborne radar set, complete and new. 20 sets, each at. \$2,350.00

SCR-545—Complete radar set, less vehicle, antenna and power plant, pretty fair condition, sold as-is at. \$1,175.00

SCR-720—Airborn radar Write

SN—RADAR—10 cm—Compact, light and portable, ranges of 5 and 20 miles. Uses 5CPI scope. Operation is from 115 volts, 60 cycle, but we can supply converter for dc operation \$750.00 ea.

MAG—10 cm. remarkable link radar, portable, operated from 6 volt battery, uses folding antenna and tripod. A pair at. \$1750.00

Also—SF, SG, SK, SO, SP, SQ, SR and Spare parts.

ANTENNA ASSEMBLY—Reflector is a lightweight parabolic cylinder, Ass'y has both manual and motor drive. Ideal unit for lbs, classroom demonstration, small craft, etc. \$49.50 ea.

Dozens of different antenna types in stock

NEW

TS-147 D TEST SET
Hard-to-get X-Band
SIGNAL GENERATOR
Now Available

Test Set TS 147 UP is a portable Microwave Signal Generator designed for testing and adjusting beacon equipment and radar systems which operate within the frequency range of 8500 MC to 9600 MC.

NEW UNUSED SURPLUS TS 259 K BAND

23400-24500 MEGACYCLES SIGNAL GENERATOR

NEW

MICROWAVE
TEST EQUIPMENT
TS148/UP
SPECTRUM ANALYZER

Field type X Band Spectrum Analyzer, Band 8430-9580 Megacycles.

Will Check Frequency and Operation of various X Band equipment such as Radar Magnetrons, Klystrons, TR Boxes. It will also measure pulse width, c-w spectrum width and Q or resonant cavities. Will also check frequency of signal generators in the X Band. Can also be used as frequency modulated Signal Generator etc. Available new complete with all accessories, in carrying case.

SPECIAL! 5,000 V. POWER SUPPLY

For IP25 Infrared Converter from 3 V. Battery Source. NEW, Complete with RCA 1654 Tube

\$990

Other test equipment used checked out, surplus

The
"KELLOGG DEHYDRATOR"

An all purpose self-reactivating dehydrating unit. To be used for removing moisture from gases. Numerous applications in the fields of Physics, Electronics and Chemistry. Dual insulated tanks with thermostatically controlled heating elements. Complete with 20 lbs. of Silica gel., heating elements, shut-off and safety valves.

BIGGEST & BEST in Surplus Communications Eqpt.!

WESTERN ELECTRIC 250/350 WATT RADIOTELEPHONE EQPT.

- ★ ALL NEW, UNUSED EQPT. NOT GOV'T SURPLUS
- ★ 30 CHANNELS TRANSMIT & RECEIVE CRYSTAL CONTROL, 2-20 MC RANGE.
- ★ MONITORS 3 SEPARATE CHANNELS SIMULTANEOUSLY.
- ★ MOTOR DRIVEN CHANNEL SWITCHING.
- ★ VOICE OPERATED CARRIER, OR PUSH-TO-TALK, AS DESIRED.
- ★ SALT AIR CORROSION RESISTANT, HERMETICALLY SEALED TRANSFORMERS, ETC.
- ★ IDEAL SUBSTITUTE FOR SCR-299, 399, or 499 EQPT.

WRITE FOR PRICES & LITERATURE

RC-263 TRANSMITTING EQPT. 50/75 W. OUTPUT, 1.5-10.0 MC, 4-CHANNELS CRYSTAL OR VFO CONTROL, AUTOMATIC DIAL CONTROLS ALL OPERATIONS, FULL REMOTE CONTROL, 100-260 V., 25 to 60 C. AC OPERATION, ETC.

Radio Transmitting Equipment DC-263 consists of Radio Transmitter BC-1100-A, Remote Control Unit RM-40-A, and Microphone T-27-Q. Radio Transmitter BC-1100-A is a four-channel crystal—or master-oscillator controlled, 75-watt radio telegraph or 50-watt radio telephone transmitter (conservative ratings). It operates in the frequency range from 1,500 kc to 10,000 kc and is suitable for remote control over two pairs of telephone lines. The radiated radio telephone signals are amplitude modulated. Remote Control Unit RM-40-A consists of a microphone amplifier, line level indicating meter, microphone supply rectifier and switching circuits, and pulse dial to control relays in Radio Transmitter BC-1100-A and performs all necessary functions, such as channel selection. Power-on or off, cv or phone, etc.

The frequency range covered by each of the four individual channels is from 1,500 to 10,000 kc. Any one of the four channels can be tuned to any frequency within these limits.

Radio Transmitting Equipment RC-263 is designed to operate on 100 to 260 volts alternating current, 25 to 60 cycles, single phase. Transmitter dimensions are: 18" H. x 40 1/2" W. x 30 1/4" D. The Remote Control Unit measures: 10" H. x 14" W. x 13 1/2" D. ALL EQPT. IS NEW-UNUSED and in original export packing. Available Complete with tubes, microphone, Instruction Book, and case of full spares which includes meters, relays, tubes, resistors, capacitors, additional microphone, etc. WRITE FOR PRICE & DESCRIPTIVE LITERATURE.

LARGE QUANTITIES

BC-669 RADIOTELEPHONES, NEW—UNUSED, 45 WATTS OUTPUT ON PHONE, 6 CHANNELS (CRYSTAL-CONTROLLED) FOR TRANSMITTER & RECEIVER.
 SCR-300 (BC-1000) Walkie-Talkies; SCR-536 (BC-611) Handy-Talkies. SPARE PARTS for both eqpts.
 BIGGEST & BEST STOCK IN: TCS Transmitters & Receivers with 12, 24, 110 DC or 110 AC Power Supplies.
 GE-10 KW 88-108 MC RF POWER AMPLIFIER. ALSO COLLINS and WILCOX TRANSMITTERS.
 SCR-284; BC-224; BC-312; 342 & 348. SCR-510, SCR-511, SCR-610, SCR-508, etc. VHF EQUIPMENT SCR-522, BC-797, SCR-624, & VHR-401A RECEIVERS.
 BC-221 FREQUENCY METERS, LIKE NEW—CHECKED OUT WITH MATCHING CALIBRATION BOOK.
 Finest Stock of X'MTTRS & RADIOTELEPHONES for FIXED STATION INSTALLATION, 50 Watts to 10 KW.

NEW RAYTHEON PRODUCTS

What's **different** about Raytheon Ceramics— custom-designed and made to your specifications

"What's the difference between your high-alumina ceramics and those made by others?" an engineer asked us at the I.R.E. Show.

"Purity—and *controlled consistency* of product at no extra cost," we told him. "We're also tube manufacturers. As you know, tubes are an area of ceramic production where the purity requirements are the most demanding in existence. That is why we can give you the highest standards of purity."

Controlled consistency is assured by the most modern ceramic plant in operation. New,

improved kilns, ball mills and spray dryers contribute to new standards of strength, seal reliability, temperature and mechanical shock resistance. Unsurpassed hardness, strict uniformity and unusual electrical performance are characteristic qualities of Raytheon ceramics.

When you need ceramic vacuum seals or ceramic parts of highest purity and uncompromising *controlled consistency*, check with Raytheon. Eleven top ceramic engineers are available to you for consultation, without obligation. Write for complete specification sheets.

4 Exclusive reasons why Sylvania's "Silver Screen 85" is the leading choice in Picture Tubes

1. Super-Aluminized Reflector—As the world's leading producer of aluminized picture tubes, Sylvania has developed exclusive processes to perfect the aluminized screen. Sylvania aluminized tubes offer up to 7 times the contrast of ordinary picture tubes.

2. New "Preferred-White" screen color. Sylvania's exclusive new phosphor blend produces an appealing screen color, preferred by leading television receiver manufacturers. It's a development made possible because Sylvania manufactures its own screen phosphors, and has full control of raw materials.

3. New controlled heater—Sylvania developments in heater coating have made possible a controlled heater warm-up time of 11 seconds. All Sylvania picture tubes now incorporate the controlled heater for use in series-string or conventional transformer circuits.

4. New "Fast-Soldered" Pins—Exclusive new Sylvania pin-soldering technique virtually fills the pin with solder. As a result, Sylvania picture tubes have super-bonded lead wire, offering superior electrical contact and stronger mechanical support.

For extra dependability and fine performance, Sylvania offers a complete line of receiving tubes and special-purpose tubes. For complete information write Department F21P,

MICROWAVE COMPONENTS

ROCKET TUBES

Sylvania Rocket Tubes are planar-electrode disc-seal triodes for use as oscillators and amplifiers at frequencies up to 3300 mc. Design permits broad band operation. Tuning is simpler and covers a greater continuous range than that of many other types of UHF tubes.

2C36—is a pulse-modulated oscillator for frequencies up to 1200 mc.

2C37—is designed for use as a c.w. oscillator up to 3300 mc. Plate disc is flat, grid disc folded.

5764—is a pulse-modulated oscillator for use up to 3300 mc.

5765—is for use as a c.w. oscillator without external feedback in the range from 900 to 3000 mc.

5767—is a c.w. oscillator for use up to 3300 mc. Both discs are folded.

5768—is intended for use as a c.w. amplifier-multiplier up to 3000 mc.

6018—is intended for use as a c.w. amplifier-multiplier up to 3000 mc.

6BA4—High gain, low noise, UHF television amplifier.

6481 (RT434)—c.w. amplifier for use up to 3000 mc.

6503—c.w. amplifier for use up to 3000 mc.

KLYSTRONS

These are reflex klystrons designed for use with external cavity resonators, affording the equipment designer wide latitude in the choice of external circuitry for both c.w. and pulsed operation. Cavities may be used whose characteristics are tailored to fit very wide-band or very narrow-band circuits.

Type No.	Mode	Frequency mc.

ELECTRONIC DIVISION LITERATURE

Germanium Diode and Transistor Applications Literature

Sylvania offers you the most complete collection of germanium diode applications ever published. "Industrial Uses for Germanium Crystals" contains 27 never-before-published circuits for industrial applications of Germanium Crystals.

"40 Uses for Germanium Diodes" covers applications in receiver, transmitter, instruments and control circuits. "Electronics Shortcuts for Hobbyists" describes applications in all types of devices of interest to the home hobbyist, "screwdriver mechanic," and electrical experimenter. "28 Uses for Junction Transistors" is a new manual of practical transistorized devices developed in Sylvania laboratories. "Crystal Diode Circuit Kinks" describes many new applications of germanium diodes in crystal meters, TV receivers, and electrical experiments. Price of each book—25¢.

Note 1—Units are matched in the forward direction at 1 volt so that the current flowing through the lower resistance unit is within 10% of that through the higher resistance unit. Ratings are shown for each diode.

Note 2—Consists of four specially selected and matched diodes whose resistances are balanced within ±2.5% in the forward direction at 1.5 volts. For additional balance, the forward resistance of each varistor pair is matched to within three ohms. Ratings shown are for each diode in free air.

Note 3—Units are tested in a circuit employing an input of 1.6 volts rms at 40 MC, 75% modulated at 400 cycles. Demodulated output across a 4700 ohm resistor shunted by a 5 µmf capacitor is a minimum of 1.55 volts peak to peak.

Note 4—Minimum specified reverse resistance applies to all points between 0 and -10 volts with 60 cps sweep.

Note 5—Consists of four specially selected diodes whose forward currents are matched within a range of 1 ma. with 1 volt applied. Ratings shown are for each diode in free air.

Note 6—The 1N82 and 1N82A are low noise and low conversion loss UHF television mixer crystals.

Note 7—Units are tested in a circuit employing a fundamental frequency of 126 MC. The rectified 3rd harmonic output is 0.4 ma. minimum.

Note 8—Minimum specified reverse resistance applies at 55°C for all points between -10V and -50V with 60 cps sweep.

Note 9—Reverse recovery time for these units is specified and defined as the time required for the diode to recover to a given reverse current when the operating voltage necessary to give 30 ma. forward conduction is rapidly switched to -35 volts.

Type	Reverse Current µa	Recovery Time usec.
1N119	700	0.5
	87.5	3.5
1N120	700	0.5
	175	3.5

Note 10—Units are tested in a circuit employing an input of 0.1 volts rms at 44 MC. Rectified output is a minimum of 140 µa with a 3600 ohm load and 165 µh shunted by 5 µmf capacitor.

Note 11—Normally supplied with 1/8" minimum leads but will be supplied without leads for clip-in applications upon request.

The polarity of all Sylvania crystals is indicated by a graphic symbol (—|◀—) on the body, the arrow of which indicates the direction of easier (conventional) current flow.

Sylvania Crystal Diodes are long-life, lightweight, heaterless components that have found hundreds of applications in clippers, limiters, discriminators and other circuits calling for low power rectification at frequencies up to several hundred megacycles. They have low shunt capacity and no contact potential.

Convenient pigtail leads eliminate the need for mounting hardware.

Sylvania Duo-Diodes consist of two matched diodes mounted in a single unit.

Sylvania Varistors, types 1N40, 1N41 and 1N42, consist of 4 specially selected and matched germanium diodes whose resistances are balanced

within ±2.5% in the forward direction at 1.5 volts. Sylvania Varistor Type 1N71 consists of 4 matched low impedance diodes, whose forward currents are within a range of 1 ma. with +1 volt applied.

Ratings shown are for each diode. Types 1N40, 1N42 and 1N71 are plug-in type; 1N41 is lug type.

NEW OCTAL SOCKET

—LETS YOU STANDARDIZE
PRINTED CIRCUIT TECHNIQUES

● Sylvania introduces a new octal socket designed for printed circuits. It incorporates the basic design features of the widely used 7- and 9-pin sockets, making it possible for you to develop new, more compact printed circuitry which can be standardized in production.

Current production can be speeded, too, by incorporating the new Sylvania printed-circuit octal socket wherever standard or compromise mountings are now being used.

Sylvania printed circuit sockets offer these important features

- All molded insulator
- Superior contact characteristics
- Top surface insulation
- Nesting for automatic feeding
- Positive orientation
- Cross-contact wiring

NEW SPECIAL SOCKETS

Neo-diheptal socket assembly for color TV picture tubes. Molded in low loss phenolic or alkyd. Compact design, only 11/16" deep. Leads can be supplied taped, stripped, twisted and solder dipped.

Counter Tube Socket with "zero-adjust" feature. Provides $\pm 10^\circ$ adjustment of socket orientation, providing for positive zero adjustment upon original installation as well as replacement.

25 YEARS

SUMMARY—Expanding technical principles, ideas and applications familiar to engineer-readers produced growth rate that suggests logarithmic progression. The business side of the industry moved rapidly ahead by capitalizing on engineering know-how

ENGINEERS involved in the design of electronic equipment should be familiar with the economics of their amazing field. The accompanying graphs show some of the strides that electronics has taken in becoming a major industry.

Any complete review of advances made in the last 25 years would require several hundred pages. But highlights of the beginning of the electronics era are interesting in at least two ways. They show, by contrast, what is now being done and what might have been done earlier, and they show things done in the

early days that still seem to be the best way today. These serve as guides for the future.

Radio

The art and industry in 1930 revolved around radio. Broadcasting was nine years old and 600 stations served the country. Commercial communications had been well established for a much longer period. Some photoelectric equipment was in use but industrial electronics was still in the cradle stage. Even so, about twelve million dollars worth of electronic equipment was purchased for industrial purposes

that year. The overall electronics business totalled 350 million dollars.

Receivers designed for home use were "all-electric" and usually employed a line-up of tuned-radio-frequency stages, a plate-circuit detector and two audio amplifier stages. Some superheterodyne receivers were available with 175-kc intermediate stages.

Modern design of the day included electrodynamic loudspeakers and push-pull output stages using transformer coupling. Some loudspeakers went as high as 12,000 cycles. Interstage r-f coupling and

ANNUAL FACTORY SALES OF RECEIVING TUBES

OF ELECTRONICS

By VIN ZELUFF and
WILLIAM G. ARNOLD

antenna coupling were problems then, the latter in view of the wide variation of L and C of the antenna that the consumer might use. Three and four-gang capacitors were the usual but five gangs were not uncommon.

The most evident new technical idea at the Trade Show in Atlantic City was the tone control.

Radio receiver sales in 1930 were 3.7 million sets. There were 29 million homes in the U.S. and only 12 million had radios. Of these only 7,700,000 had a-c sets; 4.3 million homes had battery sets. Many of these had been "electrified" with B eliminators and trickle chargers.

The RMA Annual Convention was held during the Trade Show. Some 200 companies exhibited in 30,000 sq ft of space. Officers of RMA for the year were: president, Morris Metcalf, American Bosch Magneto Corp.; vice presidents, Joseph L. Ray, Radio Corp. of

America, Ben G. Erskine, Sylvania Products Co., and Arthur L. Walsh, Thomas A. Edison Inc.; treasurer, E. A. Rauland, Rauland Corp.; Bond Geddes was re-elected executive vice president.

Tubes of the Day

Designers of home radio receivers were favoring type 27, 24 and 45 tubes but some older types, 71A, 26, 10 and 50, were still found in new models. Types 30, 31 and 32, 2.0-volt filament tubes, were brought out for battery portables. The 30 was a triode, the 31 a power triode and the 32 an r-f screen-grid type.

Screen-grid tubes in those days were often rated in amplification factor. The 32 had a factor of 440 and a mutual conductance of 550 micromhos.

Pentodes were at the drawing-board stage. A subcommittee of RMA consisting of five receiver de-

signers and five tube engineers was appointed to collect and study all data on the five-element tube and to formulate pentode standards.

The first issue of *ELECTRONICS* had an article on the split-anode magnetron by W. C. White (just now retiring in 1955) of the Vacuum Tube Engineering Dept. of General Electric. The tube was a water-cooled version and provided an output of 2.5 kw at 75 megacycles. A smaller tube provided about 10 watts at 400 megacycles. Both were operated as oscillators.

Hot-cathode mercury-vapor rectifier tubes had been available for about two years. The 866 was being used in broadcast station transmitters and is still a popular tube today, 25 years later. Its receiver counterparts, the 82 and 83, were smaller double-diode types. These were needed for the class-B audio systems designed for home receivers in the early thirties. They

EARLY RADAR

- 1922** Reflection of radio signals from steel buildings and ships noted
- 1930** Discovery that radio signals were reflected from aircraft in flight
- 1934** Experimental pulse radar system for detection of aircraft tested
- 1936** Range achieved of 40 miles over land and resolution of 500 yards
- 1938** First service radar for marine use installed on USS New York
- 1941** 20 radar sets in operation in the Fleet on Pearl Harbor Day

dropped out of wide use quickly along with that type of audio design for home sets.

Development of the hot-cathode gas diode led to the grid-controlled gas triode, the thyatron. It went to work in 1930 in motor-control circuits.

Broadcasting

Eight clear-channel broadcasting stations were operating at 50 kw and 28 stations applied to the Federal Radio Commission (preceded FCC) for permission to go to that level. WGY and KDKA planned to go to 200 kw and 400 kw respectively for experimental purposes.

Poland was building a transmitter using six 100-kw water cooled tubes to combat propaganda broadcasts from Moscow.

Tallest of the new style of vertical antennas for a-m stations was being built for WABC, Wayne, N. J. Its height was 676 feet.

Amplion Corp. announced a transverse-current microphone in which current was forced to cross the face of the device by the provision of two carbon electrodes, located near the periphery of the diaphragm, diametrically opposite each other. Between these electrodes a shallow channel was cut and filled with granules.

A fifty-kw American-built broad-

cast station, then the largest in Europe, was operating in Rome, Italy.

Industrial Electronics

Selsyns and thyratrons were used in tube control of stage lighting at the Chicago Civic Opera House.

In several cities, electrical dis-

play signs were being lighted at dusk each evening by phototubes. In steel mills, red-hot billets as they came from the rolls were being reversed by photoelectric controls.

Carrier current dispatching systems were being used on power lines by utility companies. The longest line in regular use was 445 miles.

One company at least was marketing a packaged photoelectric relay. It contained a phototube, a sensitive relay, a contactor, and an amplifier tube and was designed for operation of counters, control of mechanisms and for starting and stopping machinery.

A Westinghouse vice-president in charge of engineering placed a tiny model corner stone in position and actuated phototubes, relays and motors that caused a large crane in synchronism to swing into place the actual corner stone. The work was done at the site of a new \$2 million laboratory.

Automatic door openers operated by phototubes were demonstrated at a railway supply convention in 1930.

Measurements

An electronic colorscope for analyzing hues and matching sam-

ples, even miles apart, was shown.

Sonic and x-ray tests of steel welds were demonstrated at Lehigh University. An amplifier and loud-speaker reported strains by characteristic sounds when the wall was struck in the sonic test. The x-ray revealed hidden faults visually.

Vacuum-tube voltmeters and signal generators were battery operated.

Sound Reproduction

Audiophiles may take some comfort from the fact that the advantages of push-pull versus single-ended output were shown in curves of power and distortion published in May 1930. Push-pull output was found to be double that of a single tube provided the proper load was used, and distortion was roughly one-sixth that of a single tube.

A new phonograph pickup design featured reduction of weight on the needle to 4 ounces, while keeping the pickup head weight high enough to insure the inertia of the head would not be overcome due to needle vibration.

The number of manufacturers of sound equipment totalled 154 and sales in 1929 were 125 million dollars, largely to the movie industry. The motion picture industry supplied 22,600 theatres in the United States, of which 9,500 were equipped for sound. About 5,000 more were equipped during 1930.

Amplifier loudspeaker systems were used in factories for radio programs, phonograph records and to enable the boss to address all hands without leaving his desk.

Large-Screen Movies

Wide film for panoramic pictures was used to some extent and it was estimated that universal adoption of the panoramic picture would cost the industry one half as much as the introduction of sound. "Grandeur" film was being promoted by Fox Film Corp. and a film, "Happy Days", was shown at the Roxy Theater, N. Y. on a screen 21 by 42 feet. Sound track on the 70-mm film was 250 mils in width compared to 100 mils for standard film.

It was expected that if binaural recording and reproduction became feasible that the wide sound track

INDUSTRIAL TOE HOLD

- 1922** Locomotives first used 32-volt pilotrons to amplify block-signal-code impulses inductively picked up from tracks
- 1930** 4,500 locomotives were so equipped and 7,000 miles of track protected
- 1930** Thyratrons controlled 200 color-changing projectors in floodlighting of building
- 1930** Oil burner control by grid glow and amplifier tubes was operating in several hundred homes
- 1931** Control of cut-off knives in wrapping waxed paper on cereal boxes was established in food industry
- 1931** Continuous sheet processes were using electronic oscillators for measuring thickness of rubber, and moisture in paper
- 1931** Steam valve for power plants was controlled by audio over telephone line

would be split to allow recording and reproduction of two separate systems from the same film.

Use of color film was growing and Technicolor, Photocolor, Eastman-Sonochrome, Multicolor and Harris were overcoming technical difficulties.

Television

Although there was no television broadcasting except sporadic transmissions of an experimental nature around 100 meters, attempts were made to interest the fans of the day in purchase of equipment for closed-circuit experiments or reception of the occasional broadcasts.

At the transmitter units, a Nipkow disk scanned light from the object being televised across the sensitive surface of a phototube to obtain the video signal. At the receiver, a similar disk was synchronized to scan the light from a neon-filled lamp. Picture size for direct viewing was one or two inches on a side, the dimensions of a flat plate in the neon lamp.

The technique provided a recognizable face with 50 lines, while 72 showed marked improvement in detail. Even with the latter, the detail was insufficient to show the

division between normal teeth in a close-up of a face. It was felt that one hundred lines might constitute a television service of good quality for reproducing faces. Viewed ten to fourteen inches from the eye and one inch square, a hundred-line reproduction was said to be the minimum which might be expected to attract and hold public attention.

A typical televisor was that of Jenkins Television Corp. The kit consisted of motor-control rheostat, television lamp house and a Faraday induction motor which drove a scanning disk at synchronous speed. The disk was obtainable in 48, 60, 24, and 45-hole types with corresponding rotors for the desired number of pictures per second. Kit and television lamp (picture tube) retailed for \$50, and up.

To provide amateurs and experimenters with a basic television transmitter and receiver, Insuline Corp. of America brought out a complete unit selling under \$300. The transmitter consisted essentially of a motion-picture projector, utilizing standard 35-mm safety film. A synchronous motor operated the projector through a suitable gear reduction and the same

motor also operated a transmitting scanner.

An optical focusing system was mounted in front of the reel housing, while a condensing lens focused the scanned diverging rays into a photoelectric cell. Closed-circuit connections were made from the photocell to the receiver, which consisted of a four-stage, resistance-coupled amplifier, working into a neon lamp.

Large-screen television was demonstrated by E. F. W. Alexanderson. The size of six by seven feet for the images was made possible by use of a high-intensity arc and a light valve. The latter, a Karolus cell, changed the plane of polarization of the light beam going through it by means of an electrostatic field. The system employed a scanning disk, too.

Communications

Regular radiotelephone service was available in 1930 to London, Paris, Buenos Aires, Havana and Mexico.

Police and fire departments of 30 American cities had transmitters operating and 22 other cities held construction permits.

Facsimile reproduction of a newspaper page was accomplished

from San Francisco to Schenectady within three hours of issue from the printing press. Radio impulses were used to transmit typewritten messages from Washington to Hampton Roads, Va.

Then operated by the Department of Commerce, the Federal monitoring station opened at Grand Island, Nebraska.

Some interesting techniques were disclosed in patents granted. One covered a method of cutting off one side band of a modulated carrier by varying the transfer admittance as a function of frequency. Another described a system of transmitting broadcast matter over wires to several subscribers, using modulated radio waves and heterodyne frequencies.

Measurements of echoes on telephone lines received attention. A method of transmitting color pictures was described in another patent.

Other patents covered a remote metering system and a method of effecting grid modulation by using a transformer in the grid return circuit of an r-f stage.

Early Diathermy

While working on high-frequency oscillators, GE engineers noticed

that their feet heated rapidly, especially when they were standing on metal plates. The company physician found that when working with a six-to-eight-kilowatt generator producing 20 to 30 meter waves the blood temperature was slowly raised when the men were close to the equipment.

Further experiments deliberately produced artificial fever in man. A high-frequency oscillator was built using two 500-watt tubes and feeding two large metal plates mounted vertically on a table. The plates were connected to the ends of the tank coil. The patient was suspended on cotton tapes stretched across a wooden frame made of two-by-six timbers. Sheets of half-inch thick Celotex further surrounded the body to form a fairly airtight chamber around it.

Temperature rises to 104 F were common and, in one instance, a temperature of 106.5 F was recorded. Best results were obtained at 10 megacycles.

Dielectric Heating

Using an r-f generator of similar power, a live mouse was subjected to increasing field intensities, with consequent increases in body temperature. Soon the mouse lost its tail, but apparently without discomfort. It was a case of dehydration; the short waves had driven out the moisture and the tail shriveled and dropped away.

Using the same equipment, insects were killed, metals were melted, rats responded to insensible heat, moisture was driven out of procelain, and hibernating fruit flies were revived despite zero temperatures.

Science

A. A. Michelson repeated his famous speed-of-ether-waves experiment in a mile-long evacuated pipe laid on the ground near Pasadena, Calif.

The concept of electrons as wave motions rather than corpuscular bodies assembled in atomic solar systems was argued before the American Philosophical Society.

Electronic synthesis of heavy atoms from light ones was demonstrated before the American Chemical Society.

Military

Japanese soldiers at the Tokyo military college were conducting experiments in operating pilotless army tanks by short-wave control from behind the lines.

A squadron of British bombing planes flew 400 miles by radio control. Pilots were aboard for take-off and landing but kept hands off controls during ground-station control.

Transmission of sketch maps and pencilled notes by facsimile was accomplished from a Signal Corps plane flying along the west coast. Part of one message transmitted was "located two subs approaching Golden Gate".

Aeronautics

The 5th annual convention of the IRE was held at Toronto in 1930. The liaison committee on aeronautic radio research reported to the Assistant Secretary of Commerce for Aeronautics the value of radio to aviation and the material progress of aeronautics that could be accomplished by research in several pertinent problems. It recommended, particularly, research in the fields of transmission data on medium and high frequencies, radio re-

ceiver design, airplane direction finders, simultaneous reception of telephone and beacon service, altimeters, collision prevention, blind landing aids, characteristics of various types of fixed antennas, ice formation on antenna, ignition in-

terference problems, antenna design and location of receiver, spark-plug shielding, drag of wind-driven generators and engine-driven generator problems, including ripples and voltage variation.

A television system was applied to airplanes in flight so that the pilot might locate his position and see the landing field below him despite fog.

Now Assistant Secretary of State, Herbert Hoover, Jr. was elected president of Aeronautical Radio, Inc., formed to operate the radio divisions of the principal aviation companies.

Such was the status of the electronics industry 25 years ago. The accompanying graphs show the growth of the whole industry since then. Particularly outstanding is the progress of the past five years. The present level, if level is the right word, greatly exceeds that of the wartime peak.

That this is only the beginning, and that the next 25 years will show even greater growth, is inevitable. Much of the progress in this field will continue to be due to the efforts of engineers in developing new techniques and equipment for new applications of electronics.

TRACING ELECTRON PATHS

SUMMARY—Straight edge across nomograph shows directly the angle of reflection of an electron when angle of incidence and ratio of potentials for adjacent areas are known. Electromagnetic waves through several media are similarly traced

By WILLIAM J. SPAVEN

THE PATH of an electron through an electrostatic field may be readily determined by the repeated application of Snell's law, given the initial electron potential, the angle of incidence and the ratio of electron potential for two areas.

A simple procedure using a nomograph is outlined here. Determine the initial velocity of the electron entering the field in terms of potential V_1 . Obtain a plot^{1,2,3} of the equipotential lines of the field. Determine the angle θ_i at which the electron enters the field. This angle is measured from a line perpendicular to the boundary line at the point of entry.

Determine the average potential for the area between the first and second equipotential lines, as $V_1 = \frac{1}{2}(V_a + V_b)$. Determine the ratio of the two potentials. Referring to the nomograph, draw a straight line between the point corresponding to the angle of incidence θ_i and the point corresponding to the ratio of the two voltages. Extend the line to θ_r on the nomograph. The point of intersection gives the angle of refraction.

Repeated application of the process for succeeding areas will yield the path of the electron through the electrostatic field.

Although developed to aid in tracing electron paths and therefore useful in solving electron optics problems, the nomograph may also be used to trace paths of electromagnetic waves through several media with different wave velocity characteristics.

DIELECTRIC MIXTURE CHART

SUMMARY—Nomograph determines dielectric constant of mixture of two dielectrics when their respective dielectric constants and proportions are known. Computation is useful for filled resins used in encapsulation

By ELIO SION

PLASTIC materials used for encapsulation are often mixed with filler material such as glass fibers, asbestos, silica or alumina to reduce shrinkage and increase

dimensional stability. The dielectric constant of the resulting compound can be determined from the nomograph given here.

The law governing the di-

electric constant of a mixture of two different dielectrics is

$\log E = p_1 \log \epsilon_1 + p_2 \log \epsilon_2$ where E is the dielectric constant of the resultant mixture and p_1 and p_2 are the percentages by volume of substances with dielectric constants ϵ_1 and ϵ_2 respectively. For convenience, this nomograph assumes ϵ_1 to be the additive and to have the higher dielectric constant.

To find the dielectric constant of a mixture, find the ratio ϵ_1/ϵ_2 and enter the left-hand scale at this value. Draw a line joining this value with the percentage by volume of ϵ_1 to be added on the intermediate scale. The intersection of this line with the right-hand scale yields the factor K which is the value by which ϵ_2 is to be multiplied to give the dielectric constant of the new mixture; that is, $K\epsilon_2 = E$.

For example, to find the resultant dielectric constant of a mixture containing 10 percent rutile (TiO_2) by volume for which $\epsilon_1 = 110$, and 90 percent polystyrene for which $\epsilon_2 = 2.54$, enter the left-hand scale at $\epsilon_1/\epsilon_2 = 110/2.54 = 43.4$, join the intermediate scale at 10 percent and extend the line finding $K = 1.46$. Hence the dielectric constant of resultant mixture is $E = K\epsilon_2 = 1.46 \times 2.54 = 3.7$.

VHF TRANSMISSION LINE CALCULATOR

By A. E. SANDERSON

SUMMARY—Phase shift and attenuation introduced by transmission line connecting unknown impedance and measuring equipment can be quickly corrected by use of simplified calculator dial together with Smith or $Z-\theta$ chart. Dial is also useful in design of filters, antennas and matching networks

CORRECTION of vhf impedance measurements for phase shift and attenuation introduced by the transmission line connecting an unknown impedance with measuring apparatus can be made with the calculator shown here.

It is used in conjunction with

either a Smith chart or $Z-\theta$ chart. With this device corrected measurements may be plotted directly on the Smith chart without the necessity of reading values from a separate calculator and transcribing them. Scales not necessary for transmission line corrections are omitted for sim-

plicity on the chart below.

An impedance curve plotted on these charts is valuable in the design of vhf filters, matching networks and antennas. Such a curve will tell not only how good the network may be in terms of vswr, but with proper interpretation, will tell exactly what steps should be taken to perfect the design of the network.

Calculator Design

The transmission line calculator consists of a clear plastic disk about 8 inches in diameter with printed scales. Two D-shaped sections and a radial slot are cut out of the disk to allow marks to be made directly on the graph paper as the measurements are taken. A small hole is located at the center for a thumbtack pivot.

A scale around the outer perimeter of the calculator is marked off in units of $1/1,000$ wavelength. The scale goes from 0 to 500, since 1 revolution of the calculator corresponds to the phase-shift correction for a section of line $\frac{1}{2} \lambda$ in length. A scale along the upper edge of the radial slot from the center to the outer edge of the calculator is marked off in vswr from 1 at the center to ∞ at the outer edge. This scale is nonlinear, but may easily be calculated from the re-

lation $vswr = (1 + \Gamma)/(1 - \Gamma)$ where Γ is a linear function, being 0 at the center and 1 at the outer edge. This scale allows impedance points to be interpreted directly in terms of vswr.

A third scale extends along the lower side of the radial slot from the center to the outer edge of the calculator. This scale is marked off in db steps, starting from the outer edge as reference. Each db step represents the radial movement of a point by a given percentage of its distance from the center. Since this motion can be either toward or away from the center, no numbers appear on the scale. Lines marking 1-db steps are longer than the intermediate lines. This scale allows corrections to be made for the effect of line attenuation.

To determine proper line corrections as a function of frequency for the length of line used between the measuring equipment and an unknown impedance, the line is first terminated in a known or calibrating impedance. This may conveniently be a short circuit. The input impedance of the line is then measured at one frequency and the point is plotted on the Smith chart. The calculator is placed over the Smith chart and rotated until the slot is aligned with the point. Assuming a short-circuit termination, the phase correction for the line is read on the outer scale of the calculator at zero ohms on the Smith chart. The attenuation correction is the number of db steps between the measured input impedance point and the outer end of the scale.

This process is repeated for each frequency at which measurements are to be made and the phase and attenuation corrections recorded. The line input impedance can then be transformed to corresponding terminating impedances and plotted directly on the Smith chart.

FIG. 1—Solution of transmission line problem. Input impedance of transmission line is indicated by crosses and impedance of antenna by circles

To do this, the short-circuit is replaced by the unknown impedance and the input impedance of the line is measured at one of the chosen frequencies. The slot of the calculator is then positioned over the point representing this measured impedance. Moving outward along the slot from this point by the tabulated db step correction gives the vswr of the unknown terminating impedance. The calculator is then rotated counterclockwise by the tabulated phase correction and the chart is marked through the slot opposite the vswr previously established. The impedance represented by this point is the terminating impedance.

With lines that are several wavelengths long, some precautions should be observed. Frequencies of measurement must be accurately determined, preferably with a crystal calibrator, be-

Table I—Line Corrections for 133-mc Antenna

Frequency in Mc	Phase Correction	Attenuation Correction in Db Steps
	λ 1,000	
100	455	0.7
110	398	0.7
120	341	0.7
130	285	0.7
140	228	0.7
150	171	0.7

cause a small frequency error will result in a large error in the phase-shift correction.

Attenuation correction may become large and should therefore be determined quite accurately. For best accuracy, the calibrating impedance should have a vswr fairly close to that of the unknown impedance since the attenuation of the line is a function of vswr and will be greater for large vswr. If such a calibrating impedance is used, the line corrections must be determined by a method analogous to that described above for a short-circuit termination.

Example

As an example, consider the determination of the input impedance and resonant frequency as seen at the terminals of an experimental antenna unit mounted on a finite ground plane. The desired resonant frequency is 133 mc. The line used to feed this antenna has a characteristic impedance of 50 ohms.

Figure 1 illustrates measured data on such an antenna, plotted with the calculator. The antenna was replaced by a short-circuit and input impedance of the shorted line was measured at 100, 110, 120, 130, 140 and 150 mc. A table of line corrections was then made up (see Table I). The antenna was put back on the line, the new input impedances were measured, corrections applied and a corresponding series of five points were obtained. A smooth curve connecting these points intersects the axis of pure resistance at 46 ohms. The frequency at which this occurs is 129 mc. When the antenna was shortened to become a pure resistance at 133 mc, the vswr was 1.08.

NORMALIZED FILTER DESIGN

By SAMUEL D. BEDROSIAN and R. McCOY, Jr.

SUMMARY—Design chart for composite low-pass filters permits predetermining decibels of rejection from trial design. Six normalized designs are presented as examples to cover a practical range of stop-band loss

THERE IS NEED for a simple means of predetermining the rejection in decibels to be expected from a trial design of a composite filter to meet specific requirements.

Six normalized precut designs which cover a practical range of stop-band loss are presented.

Equal-ripple or Chebychev behavior of the stop band of a low-pass filter is illustrated in

FIG. 1—Ideal Chebychev stop-band response

Fig. 1. The attenuation loss of the filter in the stop band is al-

ways greater than a prescribed minimum loss.

The normalized curves shown in Fig. 2 are derived by conventional Zobel design to give such equal-ripple attenuation loss. Each curve is related to a ladder-filter structure consisting of one k section and a number of full m -derived sections as shown in Fig. 3A. Note that the curve numbers in Fig. 2 indicate the number of elements in the com-

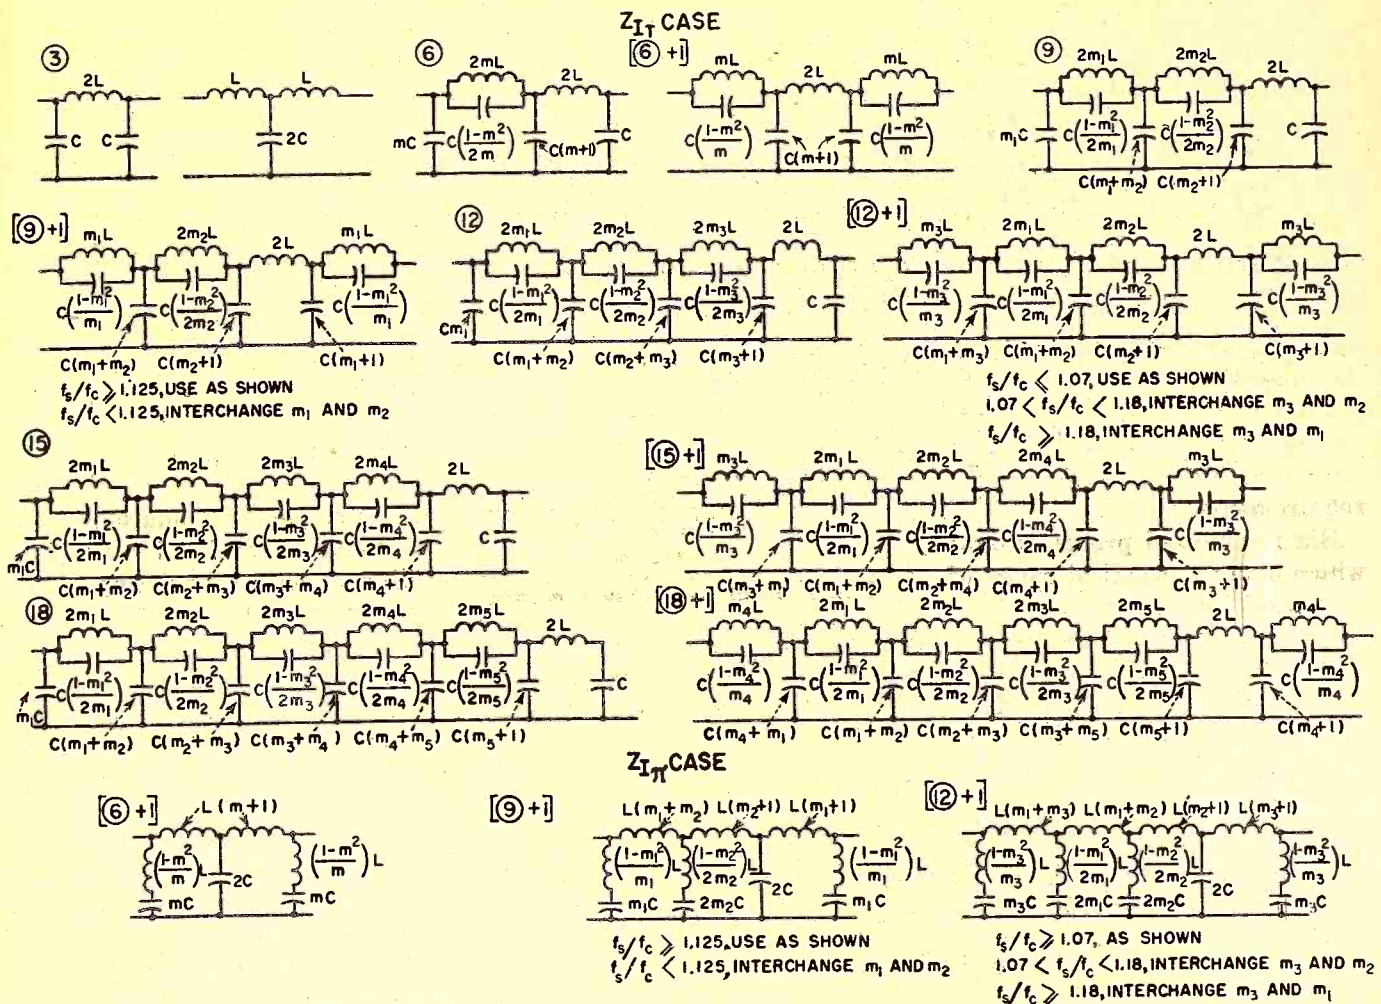

FIG. 2—Design chart. Encircled numbers on curves represent number of elements in complete filter

Table I—Filter Configurations

plete filter. Figure 3B gives the image-impedance characteristic of this network in the pass band.

To obtain a better impedance match with resistive circuits, while maintaining the same attenuation-loss characteristic, the filter section having an m value closest to 0.6 may be divided and used as terminating half-sections at each end. This will result in a complete filter network with only one additional element as shown in Fig. 4A. Various image-impedance characteristics may be obtained depending on the choice of m for the end section as shown in Fig. 4B.

Other variations in network configuration are possible, some of which are given in Table I.

Since image-parameter filters are being considered, corrections must be made to theoretical attenuation to give the insertion loss of the network for resistive

circuit applications. Insertion loss is the sum of attenuation, reflection and interaction losses.

Corrections to the stop-band loss due to reflection loss at both ends of the filter are given in Fig. 5 for the k (or $m = 1.0$) and $m = 0.6$ types of termination. Note that the reflection effect does not assist in providing the desired net loss. Thus it indicates the basis for the rule of thumb which calls for a 6-db safety factor in the attenuation characteristic when designing conventional filters.

Interaction loss is negligible for attenuation losses greater than 15 db. It is not important in the pass band, but is a factor near the cutoff frequency.

Loss Characteristic

Two design conditions must be known or established before using the curves which give the

constants needed in low-pass filter design equations. The first is the minimum attenuation loss (α_{MIN}) desired in the stop band. The second is the steepness of the transition band as expressed by f_s/f_c , the ratio of the frequency at which the minimum attenuation begins (f_s) to the cutoff frequency (f_c). The use of these two values as coordinates locates a point on Fig. 2, on or near one of the solid stop-band attenuation loss curves.

If the nearest stop-band attenuation-loss curve, with appropriate allowance for reflection loss, does not meet the design conditions either or both design conditions must be changed so the point selected will be located on an attenuation loss curve. The particular stop-band attenuation loss curve selected determines a specific filter network

given in Table I. The required m values can be read at the point selected on the curve.

The long-dash curves in Fig. 2 indicate the Q necessary in the tuned circuit, giving the first peak in the attenuation-loss characteristic to obtain the desired minimum attenuation loss in the stop band. If the necessary Q is too high to be readily obtainable, one or both design conditions must be altered to find a new point on the same or a higher-order curve. It is possible to use active circuits employing Q multipliers or transistors if the filter application warrants this added complication. Figure 6 permits calculation of loss at the nominal cutoff for other values of Q .

Figure 7 provides data to permit determination of the effect of Q on the theoretically infinite loss at the critical frequencies when additional discrimination against particular frequencies is required.

In filter work it is usual to employ essentially lossless capacitors so the Q value of the filter network is the Q of the coils used measured at the cutoff frequency. In the event that all the coils do not have approximately the same Q , the m sections with theoretically infinite frequency closest to cutoff frequency are the most critical.

The previous procedure refers

Table II—Transformations of a K Section

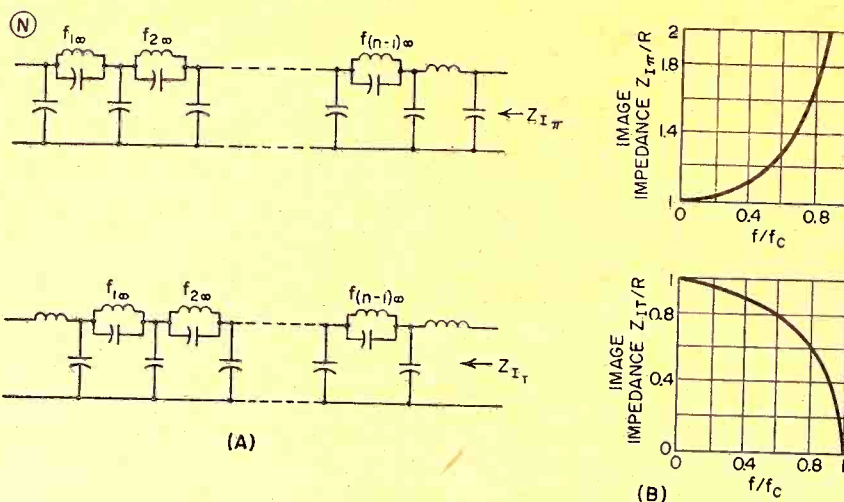

FIG. 3—Filter networks with N elements (A) and impedance characteristics (B)

FIG. 4—Filters of Fig. 3 with additional element as terminating half-section at ends

to the filter configurations of Table I. Actual choice of network depends on such considerations as the terminating impedance to be matched and the availability of inductors and capacitors. Note that the preferred combination of m values is indicated in the table for the $[(N) + 1]$ element case to give terminating half-sections closest to $m = 0.6$.

Since impedance and cutoff frequency of a normalized filter are both unity, the transformation required to get a practical filter is accomplished by making R equal to the desired nominal filter impedance in ohms and setting f_c equal to the desired cutoff frequency in cps. The data in Fig. 2 and 6 should be used as a guide to adjust the nominal

cutoff frequency to get the effective cutoff frequency of the low-pass filter.

The element values for the normalized filter networks of Table I are given by $L = R/(2\pi f_c)$ in henrys and $C = L/R^2 = 1/(2\pi R f_c)$ in farads. The m -parameter values are read from Fig. 2.

The value of $(1 - m^2)/(2m)$ which appears for every full m -derived section is given in Fig. 8.

Examples

(1) A low-pass filter is required with 40-db rejection in the stop band. The pass band extends to 2.2 kc (3-db point) and the stop band starts at 3.1 kc. Nominal impedance is 500 ohms. Compute the steepness factor

$f_s/f_c = 3.1/2.2 = 1.41$. Use the rule of thumb of 6-dB additional loss in the stop band since no specific details are available on the impedance requirement.

FIG. 5—Stop-band loss due to reflection loss at ends of filter

FIG. 6—Loss at cutoff frequency

FIG. 7—Effect of Q on infinite loss at critical frequencies

FIG. 8—Magnitude of $(1-m^2)/(2m)$ vs m

Keeping Fig. 5 in mind refer to Fig. 2 where the requirement of 46 db is met by curve 6.

Note also from Fig. 2 that the required Q is less than 10, which imposes no problem. The loss at cutoff is less than 3 db for coils with a Q of 100. Reading the curve, $m = 0.74$ for $f_s/f_c = 1.41$.

Figure 8 shows $(1 - m^2)/(2m) = 0.305$ for $m = 0.74$. For a terminating half-section, this factor is twice as large or 0.611.

Calculate the prototype inductance and capacitance, $L = 500/(2\pi \times 2,200) = 36.171$ mh and $C = 0.03617/(500)^2 = 0.1447$ μ f.

The complete filter is shown in Fig. 9A and the measured characteristics are shown in Fig. 9C. Coil Q is 50 to 55 at 2.2 kc.

(2) A low-pass filter is required to pass up to 4 kc (3-dB-down point). The stop band with a minimum of 40-dB rejection starts at 4.85 kc. The nominal impedance is 600 ohms.

Checking the curves in Fig. 2, it is found that curve (9) looks promising for 46 db attenuation $(40 + 6)$, in that it gives 1.06 for steepness factor f_s/f_c ; therefore $f_c = 4.45$ kc.

Proceeding as in the previous example, calculate the element values after reading off the m

parameters. The complete filter for $[(9) + 1]$ elements (Z_{IT} case) with $m_2 = 0.62$ and $m_1 = 0.375$ is shown in Fig. 9B. The loss at the theoretical cutoff equals 6.3 db using data found on Fig. 6 for $Q = 100$. Measured characteristics for this filter are given in Fig. 9C. Coil Q is 90 to 100 at 4 kc.

Network Transformation

Ordinary reactance-frequency transformations can be utilized to convert a low-pass filter into a high-pass, band-pass or band-stop filter. For low pass to high pass, change every coil to a capacitor and every capacitor to a coil; for low pass to symmetrical band pass, change every coil to a series-tuned circuit and every capacitor to a parallel-tuned circuit; for low pass to a symmetrical band stop, change every coil to a parallel-tuned circuit and every capacitor to a series-tuned circuit. This is shown for a k section in Table II. The low-pass frequency scale, f/f_c , is transformed to f_c/f_s for high-pass, to $[f_{sm} - (f_s f_n / f_{sh})] / f_n - f_i$ for band pass and to $(f_{sh} - f_i) / (f_{sh} - f_n f_i / f_{sh})$ for band stop.

Note in Fig. 10 that $f_c = f_{sh} - f_i$; $f_s = f_{sh} - f_{sl}$ and $f_i f_{sh} = f_s f_{sl}$.

DELAY-LINE DESIGN

SUMMARY—Simulating networks to replace delay lines may be designed from nomograph that relates time delay to inductance, capacitance and impedance of line. Expanded scales determine additional significant figures

By **JOSEPH F. SODARO**

FIG. 1—Simulated time-delay network

DELAY-LINES may be either a coil of transmission-line or an artificial line or simulating network as shown in Fig. 1.¹

The time delay in seconds for n unit lengths of line is

$$t = n \sqrt{LC} \quad (1)$$

and the characteristic impedance in ohms is

$$Z = \sqrt{L/C} \quad (2)$$

in which L is the inductance per unit length in henrys and C is the capacitance in farads.

When long delays are required from a small component, the delay network is used. In this case n is the number of sections.

The nomograph evaluates Eq. 1 and Eq. 2 for either transmission-line or lumped-constants networks. Select the desired time delay on the t scale. Pivot a straightedge about this point and read combinations of inductance and capacitance on adjacent L and C_1 scales, which give the required time delay. Next, place the straightedge on the same values on the L and C_2 scales. Read characteristic impedance in ohms where the straightedge crosses the Z scale. This procedure may be reversed if Z is the independent variable.

Each scale stem has two sides. The right-hand scales are expanded left-hand cycles. Use the left-hand scales for decimal-point location. Use the right-hand scales for significant figures.

As an example, design a 10-section line having a total delay of 5 μ sec. Since the delay per section is 0.5 μ sec, place a straightedge on 0.5 on the t scale. Pivot the straightedge about this point selecting 400 μ mf on C_1 as a value of shunt capacitance. Estimate

630 μ h where the straightedge intersects the left-hand L scale. Repeat on right-hand scales to obtain 625 μ h.

Place the straightedge on the same values on left-hand L and C_2 scales. Estimate 1,300 ohms on the left-hand Z scale. Repeat on right-hand scales to read 1,250 ohms.

POWER RATING PARASITIC SUPPRESSORS

SUMMARY—Incomplete bypassing of parasitic suppressors to harmonic currents imposes power requirements on the resistors. Chart enables designer to estimate power ratings of resistors used as parasitic suppressors

By **JOSEPH A. HUIE**

FIG. 1—R-L parasitic suppressor

ONE most common and effective method for preventing vhf parasitic oscillation in high-frequency amplifiers is use of a parallel R-L network in the plate lead of the amplifier as shown in Fig. 1. The coil is usually about 4 to 6 turns wound on a small form, often the resistor. The resistor value is normally between 50 and 100 ohms.

It is sometimes assumed that the coil at the operating frequency acts as a perfect bypass so the resistor carries no current and the wattage rating is not important. This is not strictly the case. The coil always has some reactance and at high operating frequencies this becomes an important consideration.

The curves relate the factor K

to the inductive reactance-over-resistance ratio X_L/R at the fundamental frequency, where K is proportional to the square of the effective heating current through the resistor. Curves are given for three values of conduction angle in class-C amplifier operation. The curves were computed assuming $a = 3/2$ and considering all harmonics up to the fourth.

Example

The power dissipated in the parasitic suppressor resistor is $I_{a-c}^2 RK$, where I_{a-c} is the d-c plate current in amperes, R is the resistance in ohms and K is the factor taken from the curves.

The following information is known: coil = $\frac{3}{8}$ in. dia \times $\frac{5}{8}$ in. long, 5 turns; resistor = 47 ohms; $I_{a-c} = 200$ ma.; conduction angle = 120 deg and frequency = 20 mc.

The coil inductance can be computed or measured to be about $0.115 \mu\text{h}$. Then $X_L = 2\pi fL = 14.4$ ohms and $X_L/R = 0.308$.

From the curves K is found to be 0.6, so the power dissipated in the resistor is $I_{a-c}^2 RK = 1.12$ watts.

If the amplifier is modulated 100 percent with a sine wave, the resistor power will be about 1.5 times the unmodulated power or 1.68 watts. A 2-watt resistor should then be used.

DESIGNING OVER-HORIZON

SUMMARY—Long-distance, wide-band circuits are possible using the phenomenon of tropospheric propagation provided high transmitter power and diversity receiving equipment are used. Design considerations, including antenna gain and order of diversity, show how to set up a working system with a given percentage of reliability

POINT-TO-POINT communication with ultrahigh and super-high frequency transmissions has always appeared attractive because of three important considerations: high reliability as a result of freedom from ionospheric, atmospheric and geomagnetic disturbances; large information bandwidths; and privacy.

For many years these transmissions were believed to be of service only within or slightly beyond the radio horizon, although Marconi refused to recognize this limitation. However, with advances in transmission and reception techniques and in the technology of materials, it was demonstrated that useful signals could indeed be propagated well beyond the horizon, for distances of several hundred miles, possibly by a forward-scattering mechanism or by progressive partial reflections within the troposphere.

The discussion presented here outlines briefly the design of typical point-to-point over-the-horizon cir-

cuits, with emphasis on the operating margins that must be incorporated for accommodation of various types and grades of service.

Frequency Range

The frequency range from 100 to 5,000 mc is best suited for point-to-point over-the-horizon (o-h) transmissions. The propagation mechanism still operates at frequencies as low as 30 mc, but difficulties in achieving narrow-beam antennas and intrusion of ionospheric effects raise the lower limit to about 100 mc.

The upper frequency limit is established by the heavy absorption of very short microwave radiation by water vapor in the atmosphere. Accordingly, the relationships that will be employed in discussing various system parameters as a function of frequency will be treated as valid only in the range 100 to 5,000 mc.

The path loss between two points connected by an o-h link consists of two major contributions, a free-

space loss and an over-the-horizon loss. This breakdown of the total loss is purely a bookkeeping convenience, since experimentally only the total loss can be measured. The free-space loss contains the frequency dependence, while the o-h loss (in the 100-5,000 mc range under discussion) is substantially independent of frequency.

Both losses, however, are dependent upon distance, with the o-h loss exacting the greater toll at long distances. The free-space loss represents the reduction in power density with increasing distance in free-space from the source of radiation. The frequency dependence of the free-space loss stems from the variation in collecting area (expressed in square wavelengths) of any receiving aperture of given gain as the frequency is altered.

The o-h loss is the loss remaining when the free-space loss expressed in decibels is subtracted from a median total loss (also in db) determined by a number of experiments^{1,2,3} over the frequencies and distances of interest. Various theoretical foundations for the form of the o-h loss⁴⁻⁷ have been given. It is the experimentally determined path loss that must be principally considered in the design of point-to-point o-h links.

Free-Space Loss

The free-space loss, L_{fs} , when expressed in decibels, takes the form

$$L_{fs} = 10 \log_{10} \frac{G_r G_t}{P_r / P_t} = \quad (1)$$

$$20 \log_{10} \left(\frac{4\pi d}{\lambda} \right) = 22 + 20 \log_{10} (d/\lambda)$$

FIG. 1—Free-space loss is dependent upon distance and wavelength

COMMUNICATIONS LINKS

By DAVID DAVIDSON and ALFRED J. POTÉ

where P_r is the received power at a receiving antenna of gain G_r in the direction of the link, P_t is the transmitted power delivered to an antenna of gain G_t in the direction of the link, d is the distance between terminals and λ the wavelength. Note that it is the ratio d/λ , the distance in wavelengths, that determines the character of the free-space loss as shown in Fig. 1.

Over-Horizon Loss

Path loss L_p is the sum of L_{fs} , the free-space loss and L_{oh} , the o-h loss, all quantities being expressed in decibels. The empirical formulation of L_{oh} is

$$L_{oh} = A + B(d - d_0) \quad (2)$$

where A is the o-h loss associated with the distance d_0 and B is the rate at which the o-h loss accrues with distance (attenuation rate). For present purposes, d_0 will be taken as 100 miles; the expression then becomes

$$L_{oh} = 57 + 0.13(d_{mi} - 100) \quad (3)$$

FIG. 3—Aperture-to-medium coupling loss results from failure to realize plane-wave antenna gain

FIG. 2—Over-horizon loss for typical northern U.S. overland transmission

where d_{mi} indicates that distance should be entered in miles. The attenuation rate B is dependent on the average refractive properties of the atmosphere for the path under discussion. The value 0.13 db per mile is taken as typical for overland transmission in northern U. S. A. and southern Canada. It may be as low as 0.11 db per mile for semitropical, over-water paths and as high as 0.15 db per mile for dry, arctic conditions.

Parameter L_{oh} is plotted in Fig. 2 for the case of $B = 0.13$ db per mile. For other values of B , some adjustment might be necessary for the value of A .

Total path loss L_p in decibels, can then be written as

$$L_p = L_{fs} + L_{oh} + 79 + 20 \log_{10}(d/\lambda) + 0.13(d_{mi} - 100) \quad (4)$$

Antennas

The ratio of antenna gains to the ratio of received and transmitted powers, as shown in Eq. 1, implies that transmitted power may, up to a point, be exchanged for antenna power gain. Since increasing the antenna gain results in a narrowing of the antenna beam, an exchange of transmitted power for antenna gain is accompanied by increased privacy. This is not directly evident from Eq. 1.

Assuming that paraboloidal reflector antennas of diameter D are used, with illumination efficiencies of 64 percent, numerical power

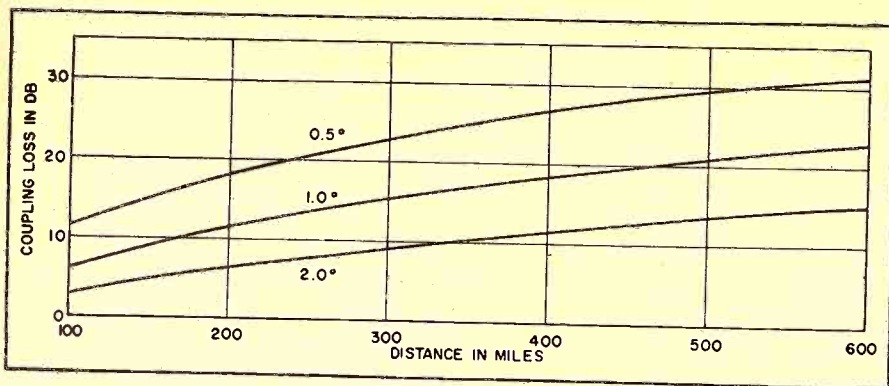

FIG. 4—Coupling loss for three different beam widths

gain is given by

$$G = 2\pi (D/\lambda)^2 \quad (5)$$

The half-power beam width in degrees, w° , is given⁷ by

$$w^\circ = 70\lambda/D \quad (6)$$

The net path loss L_{net} can then be expressed in decibels as

$$L_{net} = L_{fs} - G_s + L_{oh} \quad (7)$$

where G_s is the system gain and is the sum of the terminal antenna gains expressed in decibels. That is, for similar antennas

$$G_s = 20 \log_{10} 2\pi (D/\lambda)^2 \quad (8)$$

The relation of system gain to beam width can be expressed in decibels as

$$G_s = 89 - 40 \log_{10} w^\circ \quad (9)$$

For example, with a beam width of 1° , G_s equals 89 db; with a beam width of 2° , G_s falls to 77 db.

Thus far, the effect of increased antenna gain has been related to increased privacy and a reduction in the net path loss. When the antenna beams become extremely narrow (large apertures), the volume of the atmosphere intercepted by the beams does not contribute as much to the scattering process⁸ as it would with wider beams. The result can be regarded as an increase in o-h loss or as a failure to realize the full plane-wave antenna gain; the latter view is presently more prevalent.

This aperture-to-medium coupling loss L_c has been defined theoretically² under the assumption of identical terminal antennas. The magnitude of L_c depends on antenna beam width and distance between stations. As shown in Fig. 3, L_c is a function of w/w_a , where w is the beam width and w_a the angular distance between stations for an

assumed radius of the earth of 5,000 miles. Loss L_c is a function of distance only for a given antenna beam width.

An example of this dependence on distance is given in Fig. 4 for beam widths of 0.5, 1.0 and 2.0 degrees. It is difficult to determine L_c experimentally, but this has been done⁹ by Lincoln Laboratory, M.I.T. The results indicate that L_c is generally several decibels lower than predicted in Fig. 3 and 4. Temporal variations noted in L_c are indicated in Fig. 8 of Reference 9.

Besides increasing privacy, the narrowing of an antenna beam provides increased protection from the strong, interfering reflections caused by aircraft flying in or near the path. These reflections produce violent, rapid fading and furthermore, introduce multipath distortion that may be extremely deleterious to certain pulse transmissions and which may also restrict the effective information bandwidth.

A radio receiver amplifies and demodulates not only the input

signal but also the noise voltages generated in the antenna and in its own resistances and tubes. Since all antennas generate noise, all received signals are inherently contaminated by noise. To this minimum noise the receiver adds its own noise. As a practical matter, only the first two stages of a receiver contribute significantly to the noise output.

A measure of this additional noise output is the so-called noise factor that may be defined as the quotient of the s-n ratio at the receiver input terminals and the s-n ratio at the receiver output. When expressed in decibels it is called the noise figure F_n . The minimum attainable noise figure in a receiver depends largely on the state of the art. In general, the figure increases with frequency.

For receivers of current design, at frequencies above 100 mc, a conservative estimate of the noise figure in decibels is

$$F_n = 5.3 + 3.6 \log_{10} (f_{mc}/100) \quad (10) \\ = 3.6 \log_{10} f_{mc} - 1.9 \quad (f_{mc} \geq 100)$$

where f_{mc} is the frequency in mc.

For a frequency of 2,000 mc Eq. 10 yields $F_n = 10$ db, a figure that agrees well with recent developments¹⁰ in r-f amplifier design.

Noise appearing in a receiver when an antenna is connected may be considered as arising in a resistance equal to the radiation resistance of the antenna, assuming the antenna is not trained on a cosmic noise source. This thermal noise power as it affects the receiver output is

$$P_n = kTB \quad (11A)$$

FIG. 5—Long-term fading characteristic based on 100-mc data

FIG. 6—Short-term fading characteristic taking place within an hour

FIG. 7—Required power depends upon reliability desired

where P_n is the noise power in watts, k is Boltzmann's constant, T is the absolute temperature and B is the receiver i-f bandwidth in cps.

The minimum noise output of a receiver is proportional to the i-f bandwidth. Hence, for low noise output, the receiver must be designed for the minimum bandwidth commensurate with the rate of information involved.

As an example, assume that a proposed link is to handle a single teleprinter channel at 60 words per minute.

While in an ideal wire circuit a 60 wpm transmission would require a bandwidth of only 22.5 cps, the characteristics of practical wire transmission circuits are such that 100 cps is necessary. In a radio link more bandwidth may be used to give the required reliability in the presence of fading. For conventional frequency-shift (fsk) systems a bandwidth of about 1,000 cps is needed for a 60-wpm circuit. This value of 1,000 cps will be used as reference bandwidth B_0 .

In Eq. 11A the noise introduced by the antenna in the range of frequencies discussed is described by a temperature T which is custom-

arily taken as 60 F (289 degrees absolute). Since then $kT = 4 \times 10^{-21}$ watt-seconds, Eq. 11A becomes, if all figures are expressed in decibels

$$P_n (60F) = 10 \log_{10} B - 204 \quad (11B)$$

For the reference bandwidth B_0 . Eq. 11B becomes (relative to 1 watt)

$$P_n (60F) = -174 \text{ dbw} \quad (11C)$$

For any other bandwidth simply add $10 \log_{10} (B/B_0)$ to the right hand side of Eq. 11C. Some typical services with corresponding bandwidth figures are listed in Table I.

Signal-to-Noise Ratio

In a communications link, the transmitter not only must deliver enough signal power to overcome noise in the receivers; it must also provide enough additional signal power for acceptable readability. Readability depends upon the signal-to-noise ratio at the detector input and upon the possible improvements achieved by the method of detection for some systems²⁸ of modulation.

With frequency modulation, for example, the improvement is proportional to the square of the modulation index. For a given information rate the latter can be increased only at the expense of greater bandwidth, which in turn involves more thermal noise and hence raises the level to which a signal must rise before the improvement can be realized.

In the examples in this discussion it is assumed that an input signal-to-noise ratio of 10 db is just acceptable for reception of 60-wpm teleprinter. With other

FIG. 8—Advantage of dual diversity for teleprinter channel

Table I—Teleprinter and Voice Requirements

Teleprinter, 60 wpm, fak 425 cps	i-f band- width ¹¹	db added to -174 dbw (Eq 11C)
1 channel	1,000 cps	0
4 channels	1,700	2.3
12 channels	3,400	5.3

Voice, 4 kc per channel	Subcarrier modulat- ing fre- quency	i-f band width ¹² (mod index = 1.5)	db added to -174 dbw (Eq 11C)
12 channels	12-60 kc	468 kc	26.7
24 channels	12-108 kc	842 kc	29.3
36 channels	12-156 kc	1,220 kc	30.9

systems an adjustment of this figure will be necessary; for example, in commercial (a-m) television a signal-to-noise ratio of at least 40 db is required for high-grade service.

Fading Safety Margins

The o-h loss L_{oh} shown in Fig. 2 represents a median value obtained from experimental data. There is a long-term, seasonal fading that is not yet completely known for the entire frequency range 100-5,000 mc. However, some very complete data¹ have been obtained through transmissions in the commercial f-m band centered at 100 mc. It is this long-term fading characteristic that is displayed in Fig. 5.

Other experimental evidence indicates that the 100-mc information may be applied to much of the uhf range. As Fig. 5 shows, the long-term fading becomes less and less pronounced as the length of the link is increased. For 99-percent reliability on a long-term basis it is necessary to supply a margin of about 11 db to the median o-h loss for a path 200 miles long, while at 400 miles only 5.0 db need be supplied.

Short term, within-the-hour, fading follows a Rayleigh law; this is shown in Fig. 6 for a nondiversity system, and for a dual-diversity system that merely utilizes the better of two signals received in widely separated antennas. This technique is known as switching diversity and is less effective than combining diversity.¹⁴

In computing the total safety margin for fading, it is well to

Designing Over-Horizon Communications Links (Continued)

note that long-term and short-term fading are essentially independent. Long-term fading establishes the immediate median level upon which within-the-hour fading is superimposed. It is thus reasonable to strive for a system that will possess a given signal-to-noise ratio for at least a certain percentage of time on a long-term basis and in addition will provide perhaps equal protection on a short-term basis.

Whatever combinations of fading margins are used, there will be periods of the year characterized by low path loss during which most of the fading margin incorporated results in the realization of an unusually high within-the-hour reliability. Weighting of the two types of fading margins will be influenced by the kind of information to be transmitted and whether errors will accumulate often enough to be objectionable.

A complete consideration involves not only the fading statistics shown in Fig. 5 and 6 but also the effect of the rate of fading upon the transmitted information. The fading rate increases with frequency.¹

In an illustrative example reliability will be assumed for q percent of the time on a long-term basis along with reliability p percent of the time on a short-term basis. The two fading margins are simply added.

Terminal Loss and Site Noise

Certain other losses are always considered when designing o-h links. These are losses in transmission lines and connectors at each terminal and losses in effective operating margins owing to site noise.

Transmission line and connector losses arise from the attenuation characteristics of the lines connecting transmitter to antenna, antenna to receiver, from the power wasted in impedance mismatches at each terminal and from power lost to connector junctions. These losses generally increase with frequency. The losses at transmitter and receiver may be conveniently grouped together and denoted by L_j . A typical behavior of this loss in decibels is

$$L_j = 5 \log_{10} (f_{mc}/100) = 5 \log_{10} f_{mc} - 10 \quad (12)$$

The losses L_j should be evaluated

carefully for a given equipment, transmission line and operating condition. In practice, these losses may be found to be greater than that indicated by Eq. 12 and frequently losses that are charged mistakenly against the propagation path will be found to occur at the terminals.

At any appreciable distance from a terminal the cross section of even a narrow antenna beam is large, so that the system may become vulnerable to impulse noise generated near the path by a city, a town, a manufacturing activity or a radar transmitter. In that event, an additional amount of power may be required for the link to overcome this site noise. No simple rule exists for the margin to be allowed for this kind of noise, since

The symbols have the same meanings as before and s/n is the signal-to-noise ratio expressed in decibels. For service at least q percent of the time on a short-term and a long-term basis

$$P_q = P_m + ML_q + MS_q \quad (14)$$

where P_q is the power required for q percent reliability, ML_q is the long-term fading margin for q percent reliability and is a function of distance, MS_q is the short-term fading margin for q percent reliability.

Tabulations of the various losses and system parameters are given for 400 mc in Table II and for 2,000 mc in Table III. The results are plotted in Fig. 7 for the 90 and 99.9-percent reliabilities desired. While the tables show powers in excess of 60 dbw (1 megawatt) for

presence of obstacles in the path. It is assumed that along the path to the horizon the clearance between the path and any obstacle exceeds the radius of a first Fresnel zone. If obstacles are present, the computation must be altered as recommended^{11, 18} in the literature.

The advantage to be gained by employing dual diversity of the switching type at one terminal is illustrated in Fig. 8 for 400-mc transmission. While diversity can be regarded as a means of saving transmitted power, if it is done by spacing the receiving antennas, or as an increase in reliability, it is instructive to evaluate its advantage in extending the working distance possible with a given transmitted power.

Table IV presents the additional distances obtainable by including the diversity fading margins as scaled from Fig. 8. With higher orders of diversity and with systems that combine¹⁷ the outputs of spaced antennas, greater gains in distance or savings in power are possible.

Table IV—Additional Distance With Diversity at 400 Mc

Reliability	Order of Diversity	1 kw	10 kw	100 kw	1,000 kw
90%	1	308 mi	366 mi	420 mi	472 mi
90%	2	336	384	448	500
	Additional Distance:	28	28	28	28
99.9%	1	98	200	275	340
99.9%	2	217	300	360	420
	Additional Distance:	119	100	85	80

this will depend on the character of the noise and the way in which the improvement normally afforded by the modulating method^{11, 15} is degraded in its presence.

Illustrative Example

An organization wishes to provide over-the-horizon communication for a number of links of various lengths and has two frequency allocations at its disposal, 400 mc and 2,000 mc. Equipment can be obtained for these frequencies. The paraboloidal antenna aperture must not exceed 20 feet in diameter because of cost and mounting difficulties. It is desired to determine the power required for both 90 and 99.9-percent reliability, for 60-wpm teletype, single channel, fsk, with a frequency shift of 425 cps.

The power required, in decibels above 1 watt, for median service, 50-percent the time, is given by

$$P_m = L_{fs} + L_{oh} - G_a + L_c + L_j + F_n + (s/n) + 10 \log_{10} B_o - 204 \quad (13)$$

completeness, the curves in Fig. 7 are carried only up to this level.

Interpretation

Added gain provided by the 20-foot paraboloid at the higher frequency is hardly sufficient at the longer distances to overcome the additional free-space loss. This is the result of the increasing effect of L_c , the aperture-to-medium coupling loss for the narrowed beam.

Curves in Fig. 7 are plotted for distances from 100 to 600 miles. Some reservations should be attached to extension of the curves for distances of less than 100 miles. In that range, depending upon the height of the terminal antennas, there may be an appreciable diffracted surface wave present that would serve to widen the fading range and in any case, would provide substantially different short-term fading characteristics¹ than are indicated by Fig. 6.

The curves do not include any gains or losses incurred by the

MICROPHONE NOMOGRAPH

SUMMARY—Chart relates sound pressure level, microphone sensitivity and output in decibels and volts as aid in design of microphone systems and related equipment. Typical sound levels for common sounds are indicated

By **WILLIAM B. CONOVER**

MICROPHONE response is usually expressed in decibels referred to 1 volt per dyne/cm². Thus a microphone which produces 1 volt when exposed to a sound pressure of 1 dyne/cm²

has a response of 0 db. Most microphones are far less sensitive than this.

Unless otherwise specified, the open-circuit voltage is used in arriving at the response figure.

The nomograph is based on the definition of pressure response in the American Standard Specification for Laboratory

Standard Microphones.

Expressed symbolically, this definition becomes

$$\rho = 20 \log (e_o/p) \quad (1)$$

where ρ = pressure response, e_o = open-circuit output voltage and p = pressure in dynes/cm².

Equation 1 may be rewritten

$$= 20 \log e_o - 20 \log p \quad (2)$$

Sound pressure is commonly expressed in decibels relative to a reference pressure $p_o = 2 \times 10^{-4}$ dynes/cm². When so expressed it is called sound pressure level *SPL* and is defined by

$$SPL = 20 \log (p/p_o) \text{ decibels} \quad (3)$$

Equation 2 and 3 yield

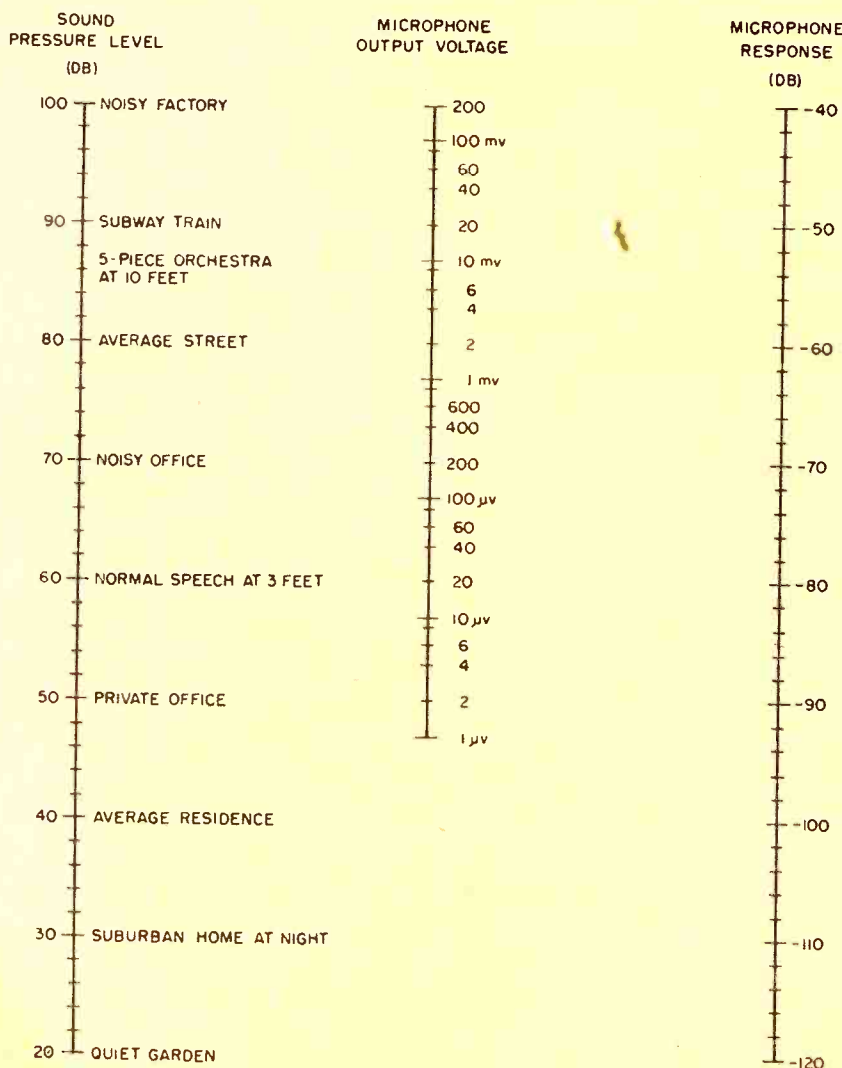

$$\rho = 20 \log e_o - SPL + 74 \text{ decibels} \quad (4)$$

Should absolute sound pressures be required, they may be filled in on the lefthand scale by noting that 100 db = 20 dynes/cm², 80 db = 2 dynes/cm², 60 db = 0.2 dyne/cm² and so forth.

A microphone with a response of -50 db is to be used to measure sound levels of 35 db or more. For what minimum input voltage should the amplifier be designed?

A straight line drawn between 35 db on the *SPL* scale and -50 db on the ρ scale intersects the e_o scale at about 35 μ v. This is the open-circuit microphone voltage.

Sound level in a jet-engine test control room is 112 db; a pneumatic chipper at a distance of 5 feet has a sound level of 122 db. At takeoff and 80 ft from the tail, an F-84 has a sound level of 130 db, all typical values.

PHASE-LINEARITY NOMOGRAPH

SUMMARY—Chart relating time delay, phase shift and frequency facilitates testing of phase-shift, band-pass and delay time characteristics of video amplifiers and other pulse circuits

By **JOSEPH F. SODARO**

IN the design of video amplifiers, i-f amplifiers, delay lines and similar circuits, it is desirable to obtain uniform gain and linear phase shift over the desired passband.

This condition of phase shift proportional to frequency may also be defined as constant time delay. If phase shift in radians is expressed as $\phi = 2\pi ft$, the expression can also be written as $t = \phi/2\pi f$.

If ϕ is proportional to frequency f , the right-hand member of the second equation is a constant. Thus, t , the time delay is a constant.¹

Large angular measurements may be simplified if frequencies corresponding to principal angles are measured. At these angles the cro pattern is a straight line or circle. Small angles can be measured by the intercept method in which the phase-angle sine equals the ratio of y -intercept to maximum-deflection values. From this, the angle can be calculated.²

As frequency is varied and angular difference observed on the cro the amount and constancy of time delay can be determined from the nomograph. Select angular difference on the ψ scale in degrees.

Draw a line to the frequency on the right-hand scale. Read time delay where the line intersects the t scale on right or left-hand scale corresponding to the f scale used. As frequency is varied, pivot a straight-edge about the time-delay value to other ϕ and f combinations. Observe the deviation from a constant time delay to determine bandpass limits of the circuit under test.

By providing limit lines on the t scale in accordance with test specifications, this chart can be used by production test personnel.

DESIGNING I-F TRANSISTOR

By ROGER R. WEBSTER

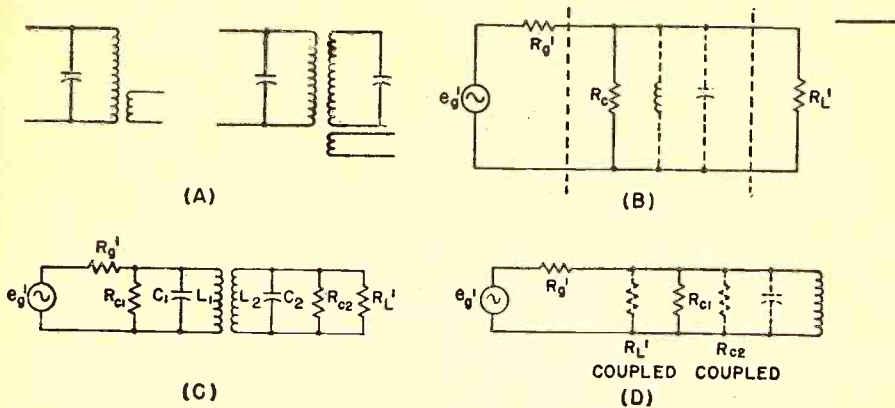

FIG. 1—Single and double-tuned transformers (A), equivalent circuit of single-tuned unit (B); schematic (C) and equivalent circuit (D) of double-tuned unit

FIG. 2—Ratio of coil reactance to generator impedance vs loaded Q

FIG. 3—Loaded Q vs 6-db bandwidth ratio for single-tuned transformers

INTERMEDIATE-FREQUENCY transformers used in vacuum-tube amplifiers are essentially independent of vacuum-tube impedances and the desired band-pass characteristics may be determined independently of vacuum-tube loading at ordinary intermediate frequencies. Grid loading is insignificant and plate loading will often be small enough to be neglected since the plate resistance of many receiving-type pentodes may be $\frac{1}{2}$ megohm or higher.

Such is not the case with transistors. The collector impedance of a high-frequency transistor such as the Texas Instruments type 225 may be as high as 100,000 ohms or more at 455 kc but the input impedance is low—of the order of 300-500 ohms, grounded emitter. Impedance matching is important to secure maximum power transfer and the band-pass characteristics of the transformer cannot be determined without considering the effects of transistor loading.

Single-tuned transformers have been widely used for transistor i-f amplifiers since for equal 3-db bandwidths they have less insertion loss than double-tuned transformers. However, where adjacent channel rejection is important, double-tuned transformers will often give less insertion loss than single-tuned transformers. Keeping transformer losses low is important with the limited gains available from present-day high-frequency transistors. Figure 1A shows some practical arrangements for both single and

TRANSFORMERS

SUMMARY—Design of tuned coupling networks for i-f transistor transformers requires matching collector and base impedances while meeting bandwidth requirements and providing minimum insertion loss. This article presents detailed procedure and curves of single and double-tuned units

double-tuned transformers.

The design equations for single and double-tuned i-f transformers are easily obtained. Consider the basic tuned coupling networks as transformers with generator and load impedances referred to the primary on a unity-turns-ratio basis and the unloaded resonant impedance of the coil as an equivalent shunt loss resistance.

Single-Tuned Transformer Design

Refer to Fig. 1B for the equivalent schematic of a single-tuned transformer:

R_g = generator impedance, R_g' = generator impedance referred to unity turns ratio, R_c = antiresonant unloaded coil impedance, R_L = load impedance and R_L' = load impedance referred to unity turns ratio.

When both R_g' and R_L' can be controlled, maximum power will be delivered to the load when $R_g' = R_L'$.

From basic theory $Q_u = R_c/X_L$ where Q_u = unloaded coil Q and X_L = coil reactance. Quantity $Q_L = (R_g' + R_c + R_L')/X_L$ = loaded circuit Q and is determined by bandwidth requirements

$$Q_L = \left[\frac{1}{\frac{1}{R_g'} + \frac{1}{R_c} + \frac{1}{R_L'}} \right] \left[\frac{1}{X_L} \right]$$

where $X_L/R_c = 1/Q_u$ and $R_g' = R_L'$ for maximum power transfer.

Solving for X_L/R_g'

$$X_L/R_g' = \frac{1}{2}[(1/Q_L) + (1/Q_u)] \quad (1)$$

Figure 2 is a plot of Eq. 1 for

various values of Q_L and Q_u . From bandwidth requirements for a single transformer $Q_L = f_o/2\Delta f$ where Q_L = loaded circuit Q, f_o = intermediate frequency and Δf = deviation from f_o giving 3-db attenuation.

When more than one transformer is involved, each tuned to the same frequency, each transformer will be down 3/T db at the Δf points, where T is the number of transformers and Δf is specified for the entire amplifier.

From a standard text on tuned circuit design¹

$$\frac{A_o}{A} = \left[1 + Q^2 \left(\frac{f}{f_o} - \frac{f_o}{f} \right)^2 \right]^{1/2}$$

where A_o/A = (voltage at frequency f_o /voltage at frequency f) and Q is the loaded circuit Q.

Letting $\Delta f = f - f_o$ and rearranging terms

$$Q_L = [(A_o/A)^2 - 1]^{1/2} \left[\frac{1 + (f_o/\Delta f)}{2 + (\Delta f/f_o)} \right] \quad (2)$$

Figure 3 is a plot of Eq. 2 for values of A_o/A corresponding to 1, 2, 3 and 4 transformers with identical characteristics. Since in circuit design, bandwidth is usually specified at the 6-db points, Fig. 3 has been plotted for 6-db bandwidth versus loaded Q rather than for 3-db bandwidth.

If transistor impedance, i-f frequency, bandwidth and unloaded coil Q are known, the reactance of the coil may be computed from the value obtained from Fig. 2 or from Eq. 1. For the usual case, the primary will be untapped. When the value of X_L obtained from Fig. 2

is less than the desired amount any greater X_L obtained from Fig. 2 is less than the desired amount any greater X_L may be used provided the driving transistor is matched by tapping down on the primary winding according to

$$n = R_o/R_g' \quad (3)$$

where R_o = transistor output impedance, R_g' = value obtained from Eq. 1 or from Fig. 2 and n = tap to overall primary turns ratio.

The secondary winding may be computed from

$$n' = R_L/R_g' \quad (4)$$

where n' = secondary to primary turns ratio, R_g' = generator impedance and R_L = transistor input impedance.

This involves an approximation, since it assumes unity coupling exists between the primary and secondary. With ordinary close coupled windings the resulting inaccuracies will be considerably less than those caused by transistor impedance variations.

Double-Tuned Transformer Design

Only the case of critically coupled coils will be considered. Less than critical coupling is not recommended, since additional transformer losses are involved. Overcoupled transformers are not subject to a simple design procedure. The circuit, with resistances referred to a unity-turns-ratio basis, is shown in Fig. 1C.

The coils and external loading are identical, so that $L_1 = L_2 = L$; $C_1 = C_2 = C$; $R_{e1} = R_{e2} = R_c = QX_L$, the antiresonant unloaded, uncou-

pled coil impedance, and $R_p' = R_L'$.

The equivalent coupled circuit diagram Fig. 1D shows the coupled impedance of R_L' and R_{c2} transferred to the primary side of the transformer.

When the coils are critically coupled, the coupled impedance is equal to the loaded primary impedance. The loaded coupled Q of either primary or secondary is $\frac{1}{2}$ the loaded uncoupled Q . The combined impedance of R_L' coupled and R_{c2} coupled is equal to the combined impedance of R_p' and R_{c1} .

Since $R_{c2} = R_{c1}$ and $R_L' = R_p'$, then R_L' coupled = R_p' and R_{c2} coupled = R_{c1} . As in the case of the single-tuned transformer, this represents the minimum insertion loss.

Let $Q_{uu} = R_o/X_L =$ unloaded, uncoupled coil Q , $Q_{Lu} =$ parallel impedance of R_p' and R_c/X_L and

$$Q_{Lu} = \left[\frac{1}{\frac{1}{R_p'} + \frac{1}{R_c}} \right] \left[\frac{1}{X_L} \right]$$

Noting that $X_L/R_o = 1/Q_{uu}$ and solving for X_L/R_p' gives $X_L/R_p' = (1/Q_{Lu}) - (1/Q_{uu})$.

This is equal to twice the single-tuned transformer value for X_L/R_p' and is indicated on Fig. 2.

To determine Q_{Lu} , an equation for coupled circuits from standard texts¹ may be rearranged

$$\frac{A_o}{A} = \left[\left(1 - \frac{Q^2 Y^2}{1 + K^2 Q^2} \right)^2 + \left(\frac{2QY}{1 + K^2 Q^2} \right)^2 \right]^{1/2} \quad (5)$$

where $Y = (f/f_o) - (f_o/f)$ and $Q = Q_{Lu}$.

For critical coupling, $K = 1/Q$ and substituting $\Delta f = f - f_o$ Eq. 5 can be solved for Q_{Lu}

$$Q_{Lu} = \left(\frac{1}{\sqrt{2}} \right) \left(\frac{f_o}{\Delta f} \right) \left[\frac{(f_o/\Delta f) + 1}{(f_o/\Delta f) + \frac{1}{2}} \right] \left[\left(\frac{A_o}{A} \right)^2 - 1 \right]^{1/4} \quad (6)$$

Figure 4 is a plot of Eq. 6 for values of A_o/A corresponding to 1, 2, 3 and 4 transformers with identical characteristics.

For transformer design, either single or double tuned, the follow-

ing information is required:

Overall amplifier bandwidth, $f = bw/2$.

Intermediary frequency, f .

Number of i-f transformers

Quantity Q_u or Q_{uu} , the unloaded uncoupled coil Q . For preliminary determination a value such as 100 may be assumed and when final determination of Q_u or Q_{uu} is made the

FIG. 4—Loaded circuit Q plotted against 6-dB bandwidth ratio for double-tuned transformers

FIG. 5—Insertion loss in db plotted against loaded circuit Q for single and double-tuned transformers

coil X_L may be adjusted to suit.

Transistor input and output impedances.

Quantities Q_L or Q_{Lu} . These may be read directly from Fig. 3 or 4. The adjacent channel attenuation may be specified if the i-f frequency is 455 kc and Q_L or Q_{Lu} read from Fig. 6.

Ratio X_L/R_p' , which may be read directly from Fig. 2.

For an untapped primary, $R_p - R_p'$ and X_L . These may be computed directly. For a tapped primary, compute N from Eq. 3 knowing X_L and R_p' .

Compute the secondary for a single-tuned transformer or tertiary for a double-tuned transformer from primary turns and Eq. 4. For double-tuned transformers, critical coupling may be determined easily since the loaded coupled Q of the primary is equal to $\frac{1}{2}$ the loaded uncoupled primary Q . Adjust the spacing between primary and secondary until this condition exists.

Transformer Losses

The Q of unloaded coils must be as large as possible if excessive insertion loss is to be avoided. Circuit efficiency is involved rather than the fraction of power coupled through the transformer.

Circuit efficiency is defined as $\eta =$ power delivered to load/maximum power available from generator = P_L/P_g , where $P_L = (e_o)^2/R_L$ with e_o the output voltage and $P_g = (e_g)^2/4R_g$ with e_g the generator voltage.

From Fig. 1B, it is found that $e_o = e_g [R_c/(2R_c + R_p)]$

Substituting these into the equation for η gives

$$\eta = \left[\frac{1}{1 + (R_o/2R_c)} \right]^2$$

which may be further simplified to give for the single-tuned case

$$\eta = [1 - (Q_L/Q_u)]^2$$

and for the double-tuned case

$$\eta = [1 - (Q_{Lu}/Q_{uu})]^2$$

Figure 5 is a plot of insertion loss for single-tuned and double-tuned transformers. It shows the importance of maintaining a high ratio of Q_u if reasonable coil losses are to be realized.

While the expression for circuit efficiency is essentially the same for both single and double-tuned transformers, the realizable efficiency depends on Q_L or Q_{Lu} . These are in

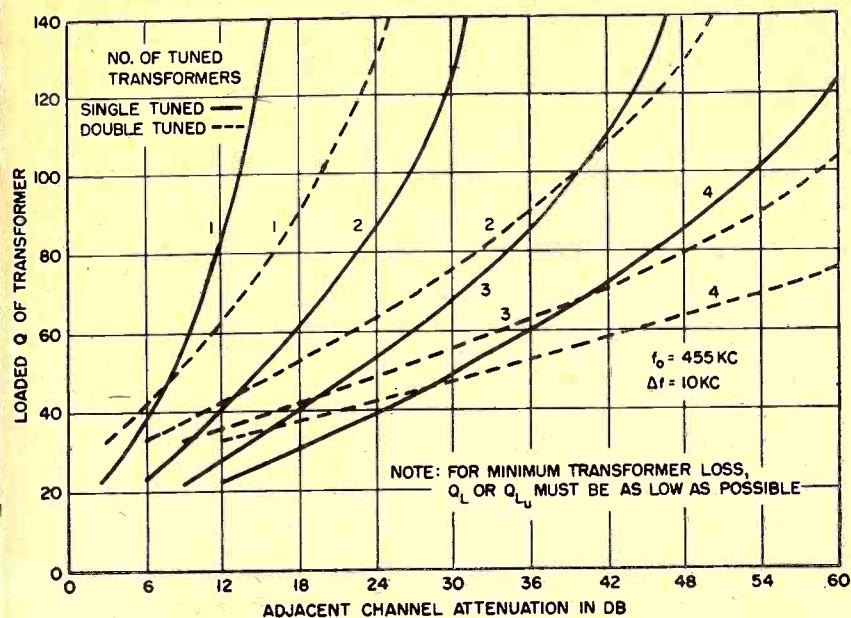

FIG. 6—Adjacent channel attenuation plotted against loaded circuit Q for single and double-tuned transformers

turn dependent on bandwidth, and except for the special case noted in the next section, Q_L and Q_{Lu} are not equal for equal bandwidths. Thus η will not be identical in the two cases.

Single-Tuned vs Double-Tuned Transformers

Ordinarily, the use of single-tuned transformers will result in less insertion loss than the use of double-tuned transformers. However, if skirt selectivity is of greater interest than bandwidth at 3-db points, double-tuned transformers may often result in less insertion loss than single-tuned transformers.

Since the expression for insertion loss involves the loaded and unloaded coil Q's and is identical for both single and double-tuned transformers, Eq. 2 and Eq. 4 may be equated, which sets $Q_L = Q_{Lu}$ and lets $Q_u = Q_{uu}$.

For $(f_o/\Delta f) > 1$

$$\frac{1 + (f_o/\Delta f)}{2 + (f/f_o)} \cong \frac{1}{2} \left(\frac{f_o}{\Delta f} \right)$$

and

$$\frac{(f_o/\Delta f) + 1}{(f_o/\Delta f) + 2} \cong 1$$

then

$$A_o/A = \sqrt{5} \quad \text{or} \quad 7 \text{ db} \quad (7)$$

The significance of Eq. 7 is that if the bandwidth is specified at the 7-db points, the insertion losses of the single-tuned and double-tuned transformers are equal, assuming Q of coils equal, since the values of loaded circuit Q are equal.

If the bandwidth is specified at points more than 7 db down from maximum, the double-tuned transformer will have less insertion loss than the single-tuned transformer and conversely

Equation 7 holds for a single transformer. When more than one transformer is used, the db points for equal insertion loss for either single or double-tuned transformers are given by $T \times 7$ where T is the number of transformers. Thus, if two transformers are used, insertion loss will be equal if bandwidth is specified at the 14-db points. Likewise, for three transformers at the 21-db points etc.

Figure 6 has been computed from Eq. 2 and Eq. 6 and shows Q_L or Q_{Lu} versus adjacent channel attenuation in db. This chart is good only for i-f is at or near 455 kc. This figure shows the superiority of double-tuned transformers if large adjacent channel attenuation is required, since much smaller insertion loss is possible than if single-tuned transformers are used.

Example

A double-tuned transformer design for a grounded-base transistor i-f amplifier was desired, having the following characteristics: number of transformers = 4; bandwidth to 6-db points = 15 kc; maximum insertion loss of transformer = 3 db; i-f frequency $f_o = 455$ kc; transistor impedances—input = 50 ohms and output = 120,000 ohms.

Calculate $f_o/BW = 455/15 = 30.4$.

Determine Q_{Lu} from Fig. 4, $Q_{Lu} = 34$.

Determine Q_{uu}/Q_{Lu} from Fig. 5, $Q_{uu}/Q_{Lu} = 3.4$.

The minimum value of $Q_{uu} = 3.4 \times 34 = 115$.

Using the values of Q_{Lu} and Q_{uu} read $\frac{1}{2} (X_L/R_o') = 0.01$.

No primary tap was desired, so that $R_o' = R_o = 120,000$ ohms. Therefore, $E_L = 2 \times 0.01 \times 120,000 = 2,400$ ohms at 455 kc and $L = 0.85$ millihenry.

After three or four attempts a 0.85-millihenry coil with Q of 115 was wound using 170 turns of No. 5-44 Litz wire with a ferrite cup core and a coil width of $\frac{1}{8}$ inch. A second identical coil was wound. Both coils were tuned to 455 kc and loaded with 120,000 ohms. By observing the Q on a Q meter, the spacing between coils was adjusted until the Q dropped to $\frac{1}{2}$ the uncoupled value at which time the coupling was critical. Spacing was $\frac{3}{2}$ inch. The turns of the tertiary coupling coil to following transistor were computed using Eq. 4, $N' = R_L/R_o' = 50/120,000 = 0.0205$. The tertiary winding is equal to 0.0205×170 or 3.5 turns. The adjacent channel attenuation for four transformers with Q_{Lu} of 34 may be read from Fig. 6 and is approximately 14 db.

MULTIPLEXING F-M

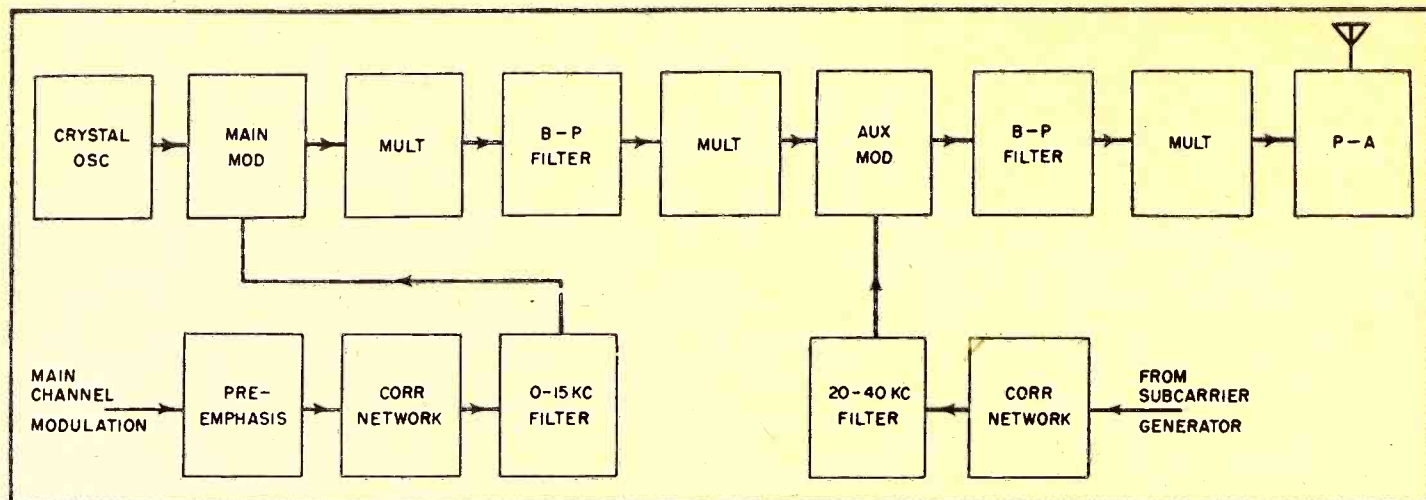

FIG. 1—Multiplex system modulator uses second phase-shift modulator at higher point in multiplication chain since less frequency deviation is needed for the subcarrier

RECENT ACTION by the Federal Communications Commission makes possible, for the first time, extensive use of frequency-modulation broadcasting facilities in special commercial applications. Any f-m broadcast licensee may now obtain a subsidiary communications authorization (SCA) that permits him to transmit for pay a simultaneous multiplex program. A special receiver is employed to detect the subcarrier modulation. Audio muting or amplification can, in addition, be actuated by transmission of ultrasonic or so-called beep tones.

While these techniques are entirely feasible, good engineering practices must be employed to avoid crosstalk between the main and subcarrier channels. In general, only skillfully designed transmitters and receivers will meet high-quality commercial performance requirements. While present legal authorization extends only to multiplexing of entertainment and news, there are no technical barriers to employment of two or more subcarriers for narrow-band communications purposes.

Experiments carried on since 1934 clearly indicate the general nature of inherent problems and their successful solutions. At that time, four different sets of signals were successfully transmitted at

By **JOHN H. BOSE**

41 mc from station W2XDG located in the Empire State Building in New York City to Haddonfield, N. J., a distance of 85 miles. These signals comprised a musical program on the main channel, a facsimile program on a superaudible subcarrier on a second channel, a synchronizing signal for facsimile on a third and a telegraph order circuit on a fourth subcarrier frequency. Amplitude-modulated subcarriers were used at this time.

In April 1935, a frequency-modulated subcarrier was employed for simultaneous transmission of two broadcast music programs. There was substantial improvement as compared with the a-m subcarrier technique and this has since become accepted experimental practice. Operations under an SCA can only be carried out using f-m subcarriers.

Transmitter Problem

Exhaustive tests continuing over the years and particularly since 1948 show that considerable care must be paid to both the transmitter and receiver. These tests were carried on by the late E. H. Armstrong assisted by the author and

others using laboratory facilities at Columbia University and those of the experimental f-m broadcast station KE2XCC at Alpine, N. J. In broadcasting where transmission is basically for entertainment, the effect of cross modulation in transmitters is much more severe than in communications. This is particularly so during the transmission of a separate program on a second channel when a diminuendo or a period of silence of that channel corresponds with a crescendo on the main channel. Experience indicates that cross talk above the level of the background noise of the second channel is objectionable. The energy content of the cross modulation with respect to signal level must be held to -50 decibels or less, or an energy content in the order of one one-hundred-thousandth part of the program level of the second channel. A ratio of 60 db or one part in a million is an attainable goal.

Since the auxiliary channel lies in the 20 to 40 kilocycle band and since the second and third harmonics of the upper half of the main channel modulation fall within that band, it will be clear that the transmitter problem will not yield readily to a solution by any direct method of modulation, for the free oscillator type of cir-

BROADCAST TRANSMITTERS

SUMMARY—Long-term practical experiments prove that the main carrier of an f-m broadcast station can be modulated ± 20 kc with an f-m subcarrier of 30 kc without affecting quality or disturbing receivers now in use. Signal-noise ratio in the auxiliary channel is better than 60 db

circuit does not lend itself to the required low-distortion level.

Present-day practice in f-m broadcast transmission uses the phase-shift method of producing frequency modulation. The invention by J. R. Day of the Serrasoid² type of modulator (which made use of an idea originally advanced by R. D. Kell) has solved, for simplex signaling, the problem of residual modulator noise in the phase-shift method of producing frequency modulation.

Background Noise

All phase-shift modulators have had to contend with transmitter background noise, which comes about basically because the limited initial frequency change that can be obtained in a phase-shift modulator entails a high degree of frequency multiplication to produce the ultimately required deviation of the transmitted wave. The high order of multiplication has the effect of enhancing those noise frequency modulations that result from the interaction of thermal and tube noise currents with the basic carrier in the oscillator and modulator circuits. An appreciable background hiss level was thus characteristic of the early phase-shift modulators (-65 db) which was reduced to values that were relatively unimportant for simplex signaling by the inventions of the double-channel, (-70 db) and the Serrasoid modulators (-80 db).

For multiplex signaling in the broadcast service, when an attempt is made to increase the frequency range of modulation, then, even with the Serrasoid modulator, the difficulty again manifests itself. This results because the fluctuation

current components lying 20 to 40 kc distant from the oscillator frequency produce correspondingly enhanced frequency deviations within the range of subcarrier channels.

These deviations, after being enhanced by the same amount of frequency multiplication that is required for a 30-cycle modulating frequency, produce a level of background noise in auxiliary channels that is not acceptable. A second difficulty incident to introducing subcarrier modulation on phase-shift modulators lies in the cross-modulation introduced in the multiplier chain because of the selectivity characteristics required of the multiplier coupling impedances.

It is essential that the lower frequency stages be sufficiently selective to eliminate the frequency-modulation superimposed on the transmitted frequency at the basic oscillator frequency, a phenomenon that has its origin in the initial multiplier stages. Hence, the selectivity that is needed in the inter-multiplier coupling stages to remove this frequency modulation results in a lack of linearity in the phase characteristic for frequencies required to carry the subcarrier and so gives rise to cross modulation in those stages.

FIG. 2—Phase-shift modulator of the type used for subcarrier multiplexing

A solution for this difficulty has been found through segregation of the modulation functions shown in Fig. 1. Here the modulation and the initial multiplications of the main channel are carried out (with certain modifications) as in simplex operation. The modulation of the auxiliary channel is superimposed at a point in the multiplication chain where relatively few additional stages are required to obtain the necessary subcarrier swing at the radiated frequency. An appropriate point for introducing the auxiliary modulation is around the 2 to 3 megacycle frequency range where the amount of phase shift necessary at the subcarrier frequency to produce the required ultimate change in frequency of the radiated wave is in the order of 1 degree.

By contrast, the shift necessary at the modulator for the main channel is approximately 150 degrees (plus and minus) to obtain the full deviation range at 30 cycles.

Linearity Solution

As a consequence, no linearity problem results from the operation of two phase-shift modulators in cascade. A phase shift modulator like that in Fig. 2 may be employed. The cross-modulation problem in the multiplier coupling stages is avoided because it is possible to make the coupling circuits of the last few multiplication stages quite broad. This can be done because the frequency modulations imposed on the transmitted carrier by the basic oscillator frequency and by the fluctuation disturbances lying in the subcarrier frequency range are no longer a problem at this

Multiplexing F-M Broadcast Transmitters (Continued)

point. The noise difficulties attendant upon operating a wide range frequency modulation system have been avoided by the narrowing down of the band width of the early multiplication stages of the main channel, so that the frequency changes introduced by thermal and tube noise component currents lying more than plus and minus 15 kilocycles from the oscillator frequency are not passed on into the auxiliary channel.

The cross-modulation problem is avoided by keeping the two channels separated until the normal circuit bandwidth requirements permit the use of circuits sufficiently wide to insure the necessary phase linearity to prevent the effect. To generate the subcarrier, a Serrasoid modulator of standard design, multiplied the frequency up to 10 to 12 megacycles and heterodyned this frequency down to the subcarrier frequency of 27.5 kc by means of an appropriate crystal-controlled oscillator. The output current was then passed through a correction network and a band-pass filter to the auxiliary modulator. Usual pre-emphasis was employed. In practice, this method of obtaining the subcarrier channel has proved stable and reliable. While somewhat more apparatus is required than for other ways of obtaining the result, it is doubtful if their reliability or performance can equal that of the present method.

Receiver

Receiving equipment used in field tests comprised r-f amplifier,

converter, crystal-controlled oscillator, five stages of 10.7-mc amplification, a double limiting system and phase-shift discriminator detector, making a total of 13 tubes.

The auxiliary channel receiver for which a circuit diagram is shown in Fig. 3 employs a 15.5-kc high-pass filter, resistance-coupled amplifier, band-pass filter and frequency-sensitive network. Following the limiters there is a gated beam detector tube followed by a 10-kc low-pass filter.

The 10-kc filter was used to prevent overload of the audio amplifier for the second channel by the subcarrier frequency. It is determined by the choice of 8 kc for the modulating band of the second channel.

In some experimental receivers, the low-pass filter configuration used to shift phase between V_{3A} and V_1 was replaced by a double-tuned capacitance-coupled circuit.

Use of multiple filter sections in the phase-shift network is predicated upon the ability to obtain straight-line phase shift over a wide range of frequency by this method as indicated in Fig. 4. The curve of interest is that marked $a = \infty$.

Where requirements are less stringent, the simplified circuit shown in Fig. 5 can be used between points A and B on Fig. 3. It would be adequate for receiving a 5-kc subchannel on which 5-percent distortion and a signal-noise ratio of about 55 db could be tolerated.

Important considerations in evaluating the system include: the overall frequency response and dis-

tortion characteristics of the auxiliary channel; the cross talk from the main channel into the auxiliary channel for different modulation levels of the main channel as a function of main channel modulating frequency; and the signal to noise ratios of the two channels for various signal input levels to the multiplex receiver.

This data is based on a main carrier frequency of 93.1 megacycles, modulated ± 20 kc, with a subcarrier of 27.5 kc. For field tests the program modulation of the main channel was held to ± 50 kc. For the auxiliary channel ± 5 kc corresponded to 100 percent modulation.

Multiplex Transmitter

Equipment was set up as shown in Fig. 1. To reduce crosstalk due to harmonics in the main channel modulating signal, a 15-kc low-pass filter was used ahead of the audio input to the main channel modulator.

The advantages of this arrangement are that the overall audio frequency response, the noise and distortion characteristics, that is, the basic performance characteristics of the main channel, remain unaffected by this modification. In addition, the signal-to-noise ratio of the auxiliary channel is improved. Crosstalk problem between the main and the auxiliary channel in the transmitter has been avoided by keeping the two channels separated until the normal circuit bandwidth requirements permit the use of circuits sufficiently wide to insure the necessary

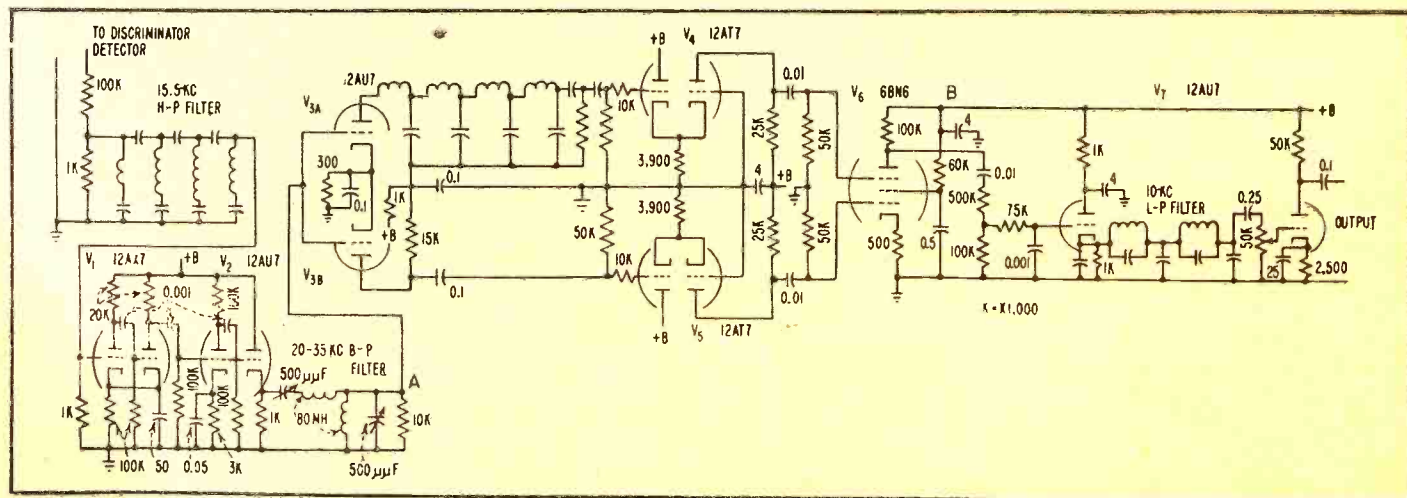

FIG. 3—Circuit diagram of the subcarrier receiver portion that follows discriminator of main-channel receiver

phase linearity to prevent the effect.

To contain the frequency range of the auxiliary channel modulation to the channel capability, an 8.5-kc low-pass filter was used ahead of the audio input to the auxiliary channel modulator.

The advantages of this method of generating the subcarrier are crystal control of the subcarrier with the attendant advantages of reliability and stability of operation and low noise and distortion characteristics of the modulator.

The usual 75 microsecond pre-emphasis circuits were available for use in both the main channel and the auxiliary channel.

Multiplex Receiver

The general arrangement of the receiving equipment used in the field tests and for making the measurements has been described under discussion of the receiver.

Field experience indicated the desirability of preceding this receiver with a fixed tuned 93.1-mc 6BK7 cascode amplifier. Such an amplifier was used ahead of the above described receiver in making the reported measurements. The input impedance of this pre-amplifier was approximately 75 ohms.

The auxiliary channel portion of the multiplex receiver which receives its signal from the main channel discriminator detector has been described.

Overall frequency characteristics of the auxiliary channel are shown in Fig. 6A. For these measurements no pre-emphasis was used in the auxiliary channel transmitter. The audio input was held constant so that for all modulating frequencies the deviation of the 27.5-kc subcarrier was ± 5 kc.

The resultant frequency characteristic was obtained by subtracting the 75 microsecond de-emphasis characteristic from the measured characteristic to take into account the effect of the 75 microsecond de-emphasis network following the detector in the auxiliary channel receiver.

The roll-off above 6,000 cycles results from the cumulative effect of the low-pass filter at the input and the band-pass filter at the out-

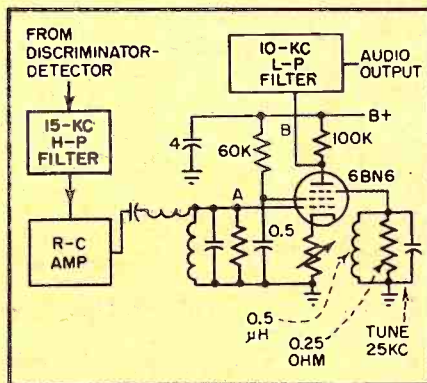

FIG. 5—Simplified receiver not used in accumulating data gives satisfactory reception

put of the auxiliary channel transmitter, the band-pass filter and the frequency-sensitive network in the auxiliary channel receiver and the 10-kc low-pass filter used to remove the subcarrier. These are factors within the control of the designer and are governed by the requirements of the system to be established.

Overall distortion characteristics of the auxiliary channel is illustrated in Fig. 6B. Distortion measurements shown were made for 100 percent and 50 percent modulation of the auxiliary channel. A Hewlett-Packard model 330B distortion analyzer connected to the audio output terminals of the auxiliary channel receiver was employed in recording these data.

A public demonstration at Columbia University was made with this receiver. Subsequent work with a similar receiver has shown that the distortion can be held to less than 2 percent for ± 5 kc deviation of the subcarrier for all the modulating frequencies involved. To do this requires closer attention to the design of the band-pass circuits and a different frequency-sensitive network. Here again, the

system requirements would control.

Crosstalk in the auxiliary channel due to main-channel modulation is shown in Fig. 6C. For these measurements the deviation of the 93.1-mc carrier by the 27.5-kc subcarrier was ± 20 kc.

To minimize the masking effects of hum and any residual subcarrier leakage in the output of the auxiliary channel receiver, a 500-cycle high-pass and a 15-kc low-pass filter were connected in cascade in the receiver output. The signal level was then established by modulating the subcarrier ± 5 kc with a 600-cycle modulating tone. With this modulation removed and no modulation on the main channel, the noise in the auxiliary channel was down 69 db.

It should be noted that for these measurements the 93.1-mc signal level across the 75-ohm input to the external cascode was approximately 1 millivolt, at which level the noise in the main and auxiliary channels is independent of receiver noise and is determined by the respective transmitters. This will be evident on examining Fig. 6D.

Main Modulation

The curves shown are for three different modulation levels of the main channel. In each case the main-channel deviation was held constant and the frequency of the main-channel modulating voltage was varied. The curves show the resultant crosstalk measured in the auxiliary channel output in db below the level established by modulating the auxiliary channel ± 5 -kc with a 600-cycle modulating tone.

These measurements were made in the laboratory at Columbia University but were spot checked at a receiving location approximately 2.5 miles from KE2XCC at Alpine, New Jersey. The site was chosen to make the measurements independent of receiver noise and possible multipath effects. No significant differences were observed between the field measurements and the curves shown in Fig. 6C.

For normal program modulation of the main channel (peak deviation ± 75 kc) the cross talk as measured with a Hewlett-Packard model 330B distortion analyzer

put of the auxiliary channel transmitter, the band-pass filter and the frequency-sensitive network in the auxiliary channel receiver and the 10-kc low-pass filter used to remove the subcarrier. These are factors within the control of the designer and are governed by the requirements of the system to be established.

Overall distortion characteristics of the auxiliary channel is illustrated in Fig. 6B. Distortion measurements shown were made for 100 percent and 50 percent modulation of the auxiliary channel. A Hewlett-Packard model 330B distortion analyzer connected to the audio output terminals of the auxiliary channel receiver was employed in recording these data.

A public demonstration at Columbia University was made with this receiver. Subsequent work with a similar receiver has shown that the distortion can be held to less than 2 percent for ± 5 kc deviation of the subcarrier for all the modulating frequencies involved. To do this requires closer attention to the design of the band-pass circuits and a different frequency-sensitive network. Here again, the

system requirements would control.

Crosstalk in the auxiliary channel due to main-channel modulation is shown in Fig. 6C. For these measurements the deviation of the 93.1-mc carrier by the 27.5-kc subcarrier was ± 20 kc.

To minimize the masking effects of hum and any residual subcarrier leakage in the output of the auxiliary channel receiver, a 500-cycle high-pass and a 15-kc low-pass filter were connected in cascade in the receiver output. The signal level was then established by modulating the subcarrier ± 5 kc with a 600-cycle modulating tone. With this modulation removed and no modulation on the main channel, the noise in the auxiliary channel was down 69 db.

It should be noted that for these measurements the 93.1-mc signal level across the 75-ohm input to the external cascode was approximately 1 millivolt, at which level the noise in the main and auxiliary channels is independent of receiver noise and is determined by the respective transmitters. This will be evident on examining Fig. 6D.

Main Modulation

The curves shown are for three different modulation levels of the main channel. In each case the main-channel deviation was held constant and the frequency of the main-channel modulating voltage was varied. The curves show the resultant crosstalk measured in the auxiliary channel output in db below the level established by modulating the auxiliary channel ± 5 -kc with a 600-cycle modulating tone.

These measurements were made in the laboratory at Columbia University but were spot checked at a receiving location approximately 2.5 miles from KE2XCC at Alpine, New Jersey. The site was chosen to make the measurements independent of receiver noise and possible multipath effects. No significant differences were observed between the field measurements and the curves shown in Fig. 6C.

For normal program modulation of the main channel (peak deviation ± 75 kc) the cross talk as measured with a Hewlett-Packard model 330B distortion analyzer

FIG. 6—Overall frequency characteristic of the auxiliary channel (A) overall distortion of the auxiliary channel for two subcarrier deviations (B) crosstalk in auxiliary channel owing to main-channel modulation (C) and signal-noise ratios of main and auxiliary channels using external cascode amplifier (D)

averages between -60 db and -65 db below full signal level for the auxiliary channel. For field tests where the peak deviation of the main channel was limited to ± 50 kc, the crosstalk was usually difficult to measure.

Signal to noise ratios of the main and auxiliary channels are shown in Fig. 6D. For these curves, the 93.1-mc carrier was deviated ± 20 kc by the 27.5-kc subcarrier.

The signal level for the auxiliary channel was established by deviating the subcarrier ± 5 kc with a 600-cycle modulating tone. The upper curve shows the noise in db below this level as a function of the signal level across the 75-ohm input to the cascode preamplifier.

The signal level for the main channel was established by deviating the main carrier ± 75 kc with a 600-cycle modulating tone. The lower curve shows the noise in db below this level as a function of the signal level as above.

For both curves the noise is measured in a 500-to-15,000 cycle band to eliminate the masking effects of hum and subcarrier leakage. This was found to be necessary in view of the high signal-to-noise ratios being measured.

It is of interest to note that for signals in excess of 500 microvolts across the input terminals, the signal-to-noise ratio of 69 db for the auxiliary channel and 77 db for the main channel are determined by the noise in the respective modulators.

Postwar laboratory development of the application of multiplexing to carriers in the 88 to 108-mc f-m broadcast band was begun in 1946, with field testing starting in the spring of 1949. This development was continued, with minor interruptions, until the present time and has included field experience with facsimile and program modulated subcarriers.

NOISE FACTOR NOMOGRAPH

SUMMARY—Chart for receiver designers relates bandwidth, noise factor and power in antenna circuit. Noise factors for both 10-db and 3-db signal-to-noise ratios may be obtained

SIGNAL-TO-NOISE RATIO sets an absolute limit to the sensitivity of a receiver. The noise generated by the radiation resistance of the antenna over the overall bandwidth of the receiver sets a limit on how far receiver noise may be reduced. Therefore, the noise factor, which compares a receiver to what could be achieved if the antenna were the sole source of noise, allows receivers with drastically different bandwidths and antennas to be compared.

Above broadcast-band frequencies, power in the antenna circuit is important since the first tube has a finite input resistance. Therefore, the dbm concept, which refers all power levels to 1 mw, is convenient.

This chart allows the designer knowing any two of the factors: power in the antenna, bandwidth, noise factor, to determine the third. The center section of the chart enables various levels in μv in the more commonly used antennas to be translated into dbm.

The following examples are for communication receivers where the convention is to specify a 10-db signal-to-noise ratio, $(S + N)/N$, and a 30-percent modulated r-f input.

(1) Input = 1.5 μv , antenna resistance = 50 ohms and bandwidth = 5 kc. Locate point A at 50 ohms and 1.5 μv . Draw a line parallel to a dbm line to intersect the reference line. Connect 5 kc on bandwidth scale with this point and project the connecting line to the noise-factor column where $\text{NF} = 6.5$ db.

By **STUART McCARRELL**

(2) Input = 4 μv ; antenna resistance = 300 ohms and bandwidth = 2 kc. Locate point B at 300 ohms and 4 μv . Draw a line parallel to a dbm line to intersect the reference line. Connect 2 kc on the bandwidth scale with this point and project to the noise-factor column where $\text{NF} = 11$ db.

The same chart, with a fixed correction factor of + 3.4 db, may be used for radar systems where a 3-db signal-to-noise ratio and a 100-percent modulated r-f are specified.

(3) If a radar receiver is to have an overall bandwidth of 4 mc and a noise factor of no worse than 15 db, what dbm sensitivity may be expected? Connect 4 mc and 11.6 db (15 db - 3.4 db) in the noise-factor column. This line (C) intersects the reference line at -70 dbm.

Noise factor scale is for 10-db signal-to-noise ratio with 30-percent modulation. Adding 3.4 db to noise factor value corrects scale for 3-db signal-to-noise ratio with 100-percent modulation

MATRIXING AND ENCODING

SUMMARY—Single encoded composite video signal appears at the output terminals of unit that combines color television signals under the NTSC system and feeds tv transmitter without distortion of any signal element

Signal at output of matrix and encoder unit in response to color-bar generator signal input

THE NTSC SYSTEM of color television transmission specifies that a composite video signal shall contain in separable form: a luminance signal which can be utilized by existing monochrome receivers to give a normal black and white picture and a two-component chrominance signal, which together with the luminance signal, conveys the complete color information.

Each of these signals is normally composed of a linear combination of the gamma-corrected red, green and blue signal outputs of a color camera, slide scanner or color-bar generator. Since the luminance and two components of the chrominance signal must be transmitted over a common communication channel, these signals must be distinguished from one another. The chrominance signal is superimposed as a modu-

lation on a subcarrier signal. The individual chrominance components are in turn distinguishable because their respective subcarrier signals are in phase quadrature.

The subcarrier must be transmitted at periodic intervals to provide the reference against which the phase of the chrominance signal may be compared. Modulation is accomplished in a balanced modulator to secure the advantages of a disappearance of the subcarrier in the absence of color. To minimize crosstalk between luminance and chrominance signals and between the components of the chrominance signals bandwidth limiting is required of the chrominance components before modulation.

The unit to be described accepts as inputs a blanking signal, a sync signal, a subcarrier signal, a burst-

key signal and the red, green and blue color signals. The unit performs the necessary operations of matrixing, modulation, bandwidth limiting, subcarrier reference-signal insertion and addition of blanking and sync signals.

Operational Stability

Feedback is used in all amplifier stages of this matrix and encoder unit to assure stability of gain and linearity of operation. In the modulator stages feedback is not easily achieved. Here the problem of stability is met by operating these stages at a high signal level. The drive signals, sync and blanking, are amplified and passed through limiting stages. This insures that the waveform and amplitude of these signals, as they appear at the output, are insensitive to amplitude and waveshape at the inputs.

NTSC Specifications

The NTSC specifications, that are relevant in the present discussion are given in Table I, Eq. 1 through 4. The symbols R , G and B represent respectively the gamma-corrected amplitudes of the signals furnished by the red, green and blue cameras and have a maximum amplitude of unity. The symbol Y represents the luminance signal, while I and Q represent the amplitudes of the two quadrature subcarrier voltages that convey color information. Finally, the symbol E represents the total video signal.

In the absence of color, $I = Q = 0$, the subcarrier amplitude is required to be zero. This feature requires that the modulators operate

as balanced modulators and hence furnish zero output in the absence of modulation. A pure luminance signal results when the R , G and B camera signals are of equal amplitude. Note in the derived relationships in Table I, Eq. 5 through Eq. 8 that $I = Q = 0$ when $R = G = B$.

The Y signal bandwidth is limited only by channel space allotted, while, as noted in Table I, the I and Q signals are restricted to bandwidths of 1.3 mc and 0.5 mc respectively.

The color-bar signal chart of Table II specifies the amplitudes of camera signals that give rise to maximum amplitude of the color signals listed in the column labeled signal. The subcarrier phase is specified with respect to the phase of the reference burst whose phase is arbitrarily specified to be 180 deg. The information in the last two columns of the chart is also given as a sinor diagram in Fig. 1.

In Fig. 2 the appearance of the composite video signal on a line basis, that is, from one horizontal sync pulse to the next is shown. The solid line represents the luminance signal which serves as the pedestal upon which the subcarrier signal is superimposed. The dotted lines represent the peak positive and negative excursions of the subcarrier signal. The reference phase burst is nominally eight cycles in duration and sits on the back porch of the horizontal blanking pulse. For convenience, black level has been set arbitrarily at zero. The small separation between blanking level and black level is referred to as set-up.

Matrixer and Encoder

Each of the camera input signals is fed directly to the Y -matrix as shown in Fig. 3. The Y -matrix, composed purely of resistors, provides at its output a linear combination of the R , G and B signal, which is proportional to the signal Y as given in Table I. From Eq. 5 and 6 note that it is possible to form I and Q signals in a matrix, the input signals to which are the R , G and B signals. Such an arrangement would require the use of two inverting amplifiers to provide the signals $-G$ and $-B$.

These inverting amplifiers would then be required to have a high de-

gree of gain stability and freedom from distortion. The gain stability is needed to assure accuracy in the matrixing. Freedom from distortion is required so that $I = Q = 0$ when $R = G = B$. If either of the inverting amplifiers produces some harmonic components of the input signals, these harmonic components will constitute a residual in the I and Q channels when, in principle, no chrominance signal should be present. Thus the I and Q signals are formed on the basis of the alternative formulations given by Eq. 7 and 8. Now only the Y signal need be inverted.

The Q signal from the Q -matrix is passed through a bandwidth-limiting filter and then into the Q amplifier. The signal is amplified and converted finally into the symmetrical signal required for the push-pull operation of the Q modu-

FIG. 4—Burst signal generated by simultaneous unbalance of the I and Q modulators

lator. The I signal from the I -matrix is treated in an identical fashion with the single exception that the I signal passes additionally through a length of delay cable. This delay is required because the delay in the Q filter is appreciably larger than the delay through the I filter. The NTSC specifications require that all components that contribute to the final video signal must be delayed by an equal amount to a tolerance of $\pm 0.05 \mu\text{sec}$. This requirement also accounts for the delay introduced into the sync, blanking and burst-key channels.

In addition to the I and Q video signals, which are fed to their respective modulators, each modulator also receives a push-pull 3.58-mc subcarrier signal. This subcarrier signal, provided by a color sync generator, is amplified and limited in a two-stage tuned amplifier so its amplitude at the modu-

lators is independent of variations at the subcarrier input jack. The subcarrier is applied directly to the I modulator and phase shifted by 90 deg before application to the Q modulator.

The output of each modulator is a balanced, a-m signal. The amplitude in one case is proportional to the I signal; the amplitude in the other case is proportional to the Q signal. The two outputs are added in a common plate load. Since the two outputs are in quadrature, the resultant signal is one that is modulated in both amplitude and phase. The phase indicates the relative amounts of I and Q while the amplitude, $(I^2 + Q^2)^{1/2}$ is related to the amount of chrominance signal. For a purely black and white scene there would be no output from the modulators and a signal would appear only in the luminance channel.

Owing to the slight but inevitable nonlinearity of operation of the modulators, second and higher harmonics of the subcarrier are generated, which must be eliminated. For this purpose, the modulated subcarrier is passed through a low-pass filter. The frequency response from the plates of the modulators to the composite video output jack is uniform to within 1 db up to 5 mc and negligible at 7.16 mc ($2 \times$ subcarrier) and thereafter.

The color burst constitutes the phase reference for the chromi-

chrominance signal. The NTSC specifications require that on a sinor diagram on which the phase of the burst is 180 deg, that the phase of a pure Q signal shall be 33 deg while the phase of a pure I signal shall be (33 deg + 90 deg) = 123 deg. These phase relations are indicated in Fig. 4. A color burst of proper phase can be generated by unbalancing simultaneously the I and Q modulators so that the relative amplitudes of the modulator outputs are related by the equation

$$\frac{(\text{Burst})I}{(\text{Burst})Q} = -\tan 33 \text{ deg}$$

The burst-key pulse is furnished by a color sync generator and has a duration of nominally eight cycles of the subcarrier signal. This color pulse is passed through an impedance-matching cathode follower into a delay cable and then through a shaping amplifier. The signal then proceeds through a gain-and-phase-control amplifier. This amplifier provides two burst-pulse outputs and has provision for adjusting independently the relative amplitudes and overall amplitudes of the burst-pulse outputs. The burst pulses are then injected into the I and Q amplifiers through a pair of buffer amplifiers.

Sync and blanking signals are passed through shaping amplifiers to make them independent of the input amplitudes, then mixed to-

gether and added to the Y signal. This composite Y signal is delayed, further amplified and added to the chrominance signal. This forms a composite video signal that is delivered to the output jack through an output amplifier. This output amplifier is adjustable in gain, has excellent linearity and will furnish a 1.4-volt peak-to-peak signal across a 75-ohm load. The output impedance is 75 ohms.

Synchronous clamping circuits are employed at the input to the output amplifier and at the video inputs to the modulators.

Video Amplifiers

Long-time stability results in large measure from use of nega-

tive feedback in all video amplifiers. With the exception of the output stage all are of the form shown in Fig. 5A. The merits of this stage with respect to stability and linearity are apparent through a comparison of the characteristics of this stage with a conventional stage of video amplification as shown in Fig. 5B. The conventional stage has a nominal gain, $A = -g_m R_L$ and an upper 3-db frequency, $f_2 = (2\pi R_L C_o)^{-1}$, C_o being the total capacitive loading of the stage. The cathode compensated stage of Fig. 5A when adjusted so that $R_k C_k = R_L' C_o$ has a gain and 3-db frequency given respectively by

$$A_c = \frac{g_m R_L'}{1 + g_m R_k} \text{ and } f_{2c} = \frac{1 + g_m R_k}{2\pi R_L' C_o} \quad (9)$$

Note from Eq. 9 that in both cases the gain-bandwidth product is the same, $A f_2 = A_c f_{2c}$.

If R_L' in the cathode compensated amplifier is selected to be $R_L' = k R_L$ and R_k is selected so $g_m R_k = k - 1$, then, from Eq. 9, the gain and bandwidth of the compensated stage will individually be equal to the gain and bandwidth of the conventional stage. In the conventional stage a given percentage variation in g_m will produce an equal percentage variation in gain. In the compensated stage however the fractional change $\Delta A_c / A_c$ in gain resulting from a fractional change $\Delta g_m / g_m$ in transconductance is given by

$$\frac{\Delta A_c}{A_c} = \frac{1}{k} \frac{\Delta g_m}{g_m} \quad (10)$$

This result follows from the gain

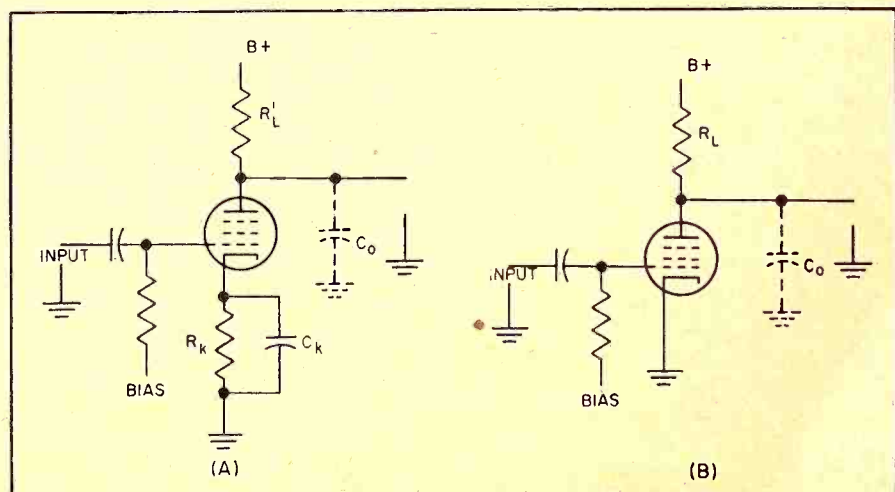

FIG. 5—Cathode-compensated amplifier stage (A) and conventional stage (B)

expression in Eq. 9. The principal source of gain instability in a video amplifier is the variation of g_m resulting from tube aging. Equation 10 indicates that the modification of a conventional amplifier in accordance with the procedure given above will preserve gain and bandwidth and reduce gain drift by the factor k .

Another advantage of the use of cathode compensation is a reduction of the nonlinearity of the amplifier. In a conventional amplifier nonlinearity of operation results essentially from the fact that the transconductance is a function of tube current and that, as a consequence, the amplifier gain varies over the range of the signal excursion.

Reduction of distortion may also be seen from the following considerations. Suppose that a peak-to-peak output signal E is required. In a conventional amplifier the tube must swing through a current range ΔI such that $R_L \Delta I = E$. In the compensated amplifier, since $R_L' = kR_L$, the tube is only required to swing through a current range $\Delta I/k$ and

hence through a correspondingly smaller range of transconductance.

The output amplifier is of the type developed by Peterson and Sinclair and is illustrated in Fig. 6. Tube V_1 serves as a phase inverter to provide push-pull signals to the grids of V_2 . In the quiescent condition the currents through V_{2A} and V_{2B} are equal and the load current is zero. A signal excursion at the grids of V_2 causes a current change, say ΔI , in V_{2A} and a current change $-\Delta I$ in V_{2B} . The difference current $2\Delta I$ flows through the load. Thus, the output tubes operate effectively in push-pull with a consequent reduction in even harmonic distortion. At the same time the circuit provides the convenience of a single ended output.

Shaper Amplifiers

Shaper amplifiers are used in this unit to standardize certain signals: blanking; sync; and the burst-key signal. The shaper chain shown in Fig. 7 is typical. Composite blanking is fed to the triode section of the 6U8 tube whose output is sufficient to drive the pentode section from clamp to beyond cutoff. The positive peaks of the output of the pentode are clean, free of overshoots and yet sharply rising owing to the rapidity with which the tube was driven to cutoff. The final stage of this chain, V_2 , is driven from zero bias to beyond cutoff. Direct coupling to the grid of this stage insures that no overshoots will be generated due to grid-current charging of coupling capacitors. The output of this stage is clean on both ends, independent of the amplitude of the

input blanking signal and suitable for mixing into the luminance channel. Gain control of the signal is accomplished by varying the screen voltage of V_2 , which controls the plate-current swing for a given grid-voltage swing.

The balanced modulator provides an output subcarrier signal whose amplitude is proportional to the video input signal and is zero when the video signal is zero. The basic modulator circuit is shown in Fig. 8.

If the two tubes are operating identically, and if the input signals are perfectly balanced, there will be zero output in the common plate load. If, due to asymmetries of circuit components or tubes or unbalance of subcarrier signals, output is obtained for zero video input, control R_2 may be adjusted to give zero output. If an unbalance exists that results in a video signal appearing at the output the video gains of the two sides may be equalized by adjusting R_1 .

Varying the bias on grid 1 affects sharply the total space current. Grid 3 controls the partition of this current between plate and screen. For a given voltage swing on grid 3 the plate-current swing will be greater if the total space current is greater and smaller if the space current is smaller. Hence R_2 , which controls the grid-1 biases, may be used to control the subcarrier output of each side. Changing the bias on grid 1 also changes the video gain of the tube and this appears as a secondary effect.

Adjusting R_1 varies the amount of cathode degeneration of the video gain of each side and there-

FIG. 6—Composite video output amplifier circuit

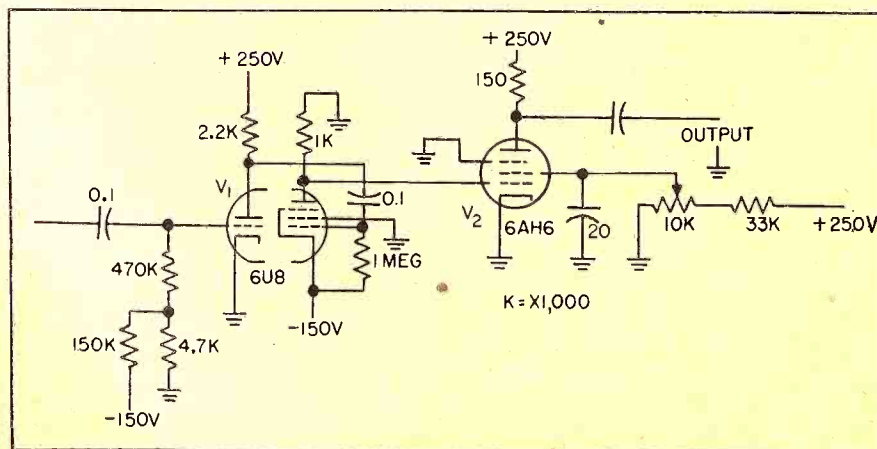

FIG. 7—Composite blanking is fed to the grid of V_1 of the shaper-amplifier chain

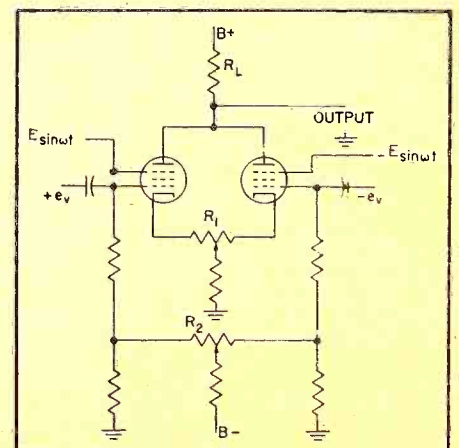

FIG. 8—Basic balanced modulator

fore acts as a video balance. However, it also affects the net grid-1 bias and therefore has the secondary effect of influencing the sub-carrier balance.

Synchronous Clamping

A modulator must provide zero subcarrier output during the blanking interval of its video input. Hence, during this blanking interval the two first grids of a modulator must return to the same voltage level. However, the chroma amplifiers are a-c coupled and the absolute voltage level at the modulator grids individually will be a function of the chrominance-signal duty cycle.

Provision is therefore required for resetting both modulator grids to some common reference voltage during the blanking interval. The problem may not be solved through the use of d-c coupled amplifiers, since the *R*, *G* and *B* camera-input signals are a-c coupled. An examination of Eq. 7 and 8 in Table I shows that the *I* and *Q* signals may make either positive or negative excursions with respect to the zero voltage blanking level and therefore conventional d-c restoration is not suitable. The synchronous clamping circuit of Fig. 9 provides a satisfactory system of d-c restoration.

During the unblanked portion of the line, the diodes are held non-conducting by voltages developed across capacitors C_1 and C_2 . During the blanking interval, pulses are applied to the diodes that force them into conduction and thereby connect the modulator grid through the conducting diodes and resistors *R* to the reference voltage.

If the two clamp signals are alike (but opposite in polarity) there will be no net clamp signal appearing at the modulator grid. Any difference in rise and fall times between the pulses will result in spikes appearing at the modulator grid. Any difference in shape of pulse tops will appear as signal at the modulator grid. Significant differences in pulse amplitude are tolerable.

To obtain pulses as nearly alike as possible, a special pulse transformer has been designed having a pair of bifilar-wound output windings. Two other windings in the

FIG. 9—Synchronous-clamp circuit

transformer are used in a conventional synchronized blocking-oscillator circuit. The synchronizing signal for the blocking oscillator is obtained from composite sync, which has been suitably delayed to match the delays in the chrominance and luminance channels. The blocking-oscillator timing has been so adjusted that, while it is easily synchronized by pulses occurring at line rate, it behaves as a 2-to-1 divider during the interval of the equalizing and serrated vertical pulses. The advantage of this 2-to-1 division is that it avoids a 60-cycle component in the clamping signal.

A synchronous clamp is also used at the grid of the output stage to minimize the required dynamic range of the output amplifier. If the signal applied to this amplifier were a-c coupled in conventional fashion, the average voltage level at the amplifier input would always be zero. As the duty cycle of the signal varies from one extreme to the other, the signal excursion with respect to zero goes positive or negative by an amount equal to the peak-to-peak voltage of the signal. Hence the amplifier is required to handle linearly a signal that is nominally twice the peak-to-peak input amplitude. Where linearity is at a premium, such operation is wasteful. The situation is corrected through the use of a synchronous clamp that restores the voltage at the output amplifier grid to a fixed reference at the end of each line.

The phase-shift circuit is shown in Fig. 10. A signal $E \sin \omega t$ is converted to a pair of push-pull signals by means of a bifilar-wound transformer LL' . To obtain a signal 90-deg out of phase, the original signal is fed to a series resonant circuit LC . The voltage across coil L will lead the input signal by 90 deg. The voltage across L will equal

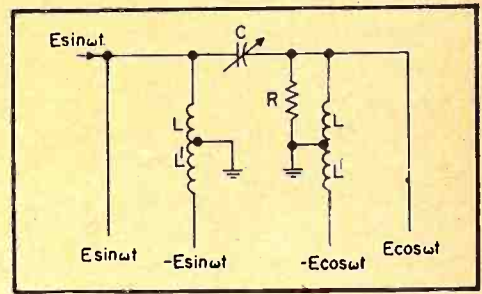

FIG. 10—Ninety-degree phase shift circuit

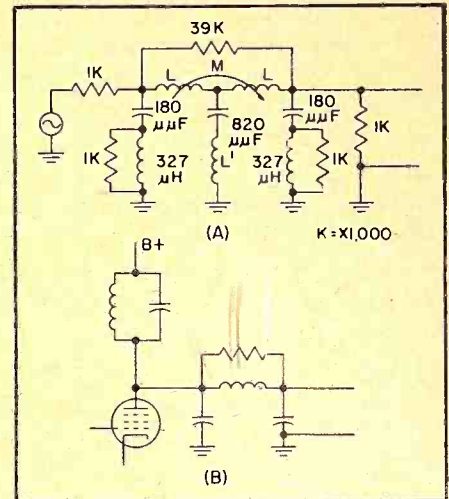

FIG. 11—*Q*-channel filter has Z_0 of 1,000 ohms (A) and *I*-channel filter (B)

Q times the input voltage. To make the output equal to the input we make $Q = 1$, that is, $R = X_L$. The actual calculation of R , L and C is complicated by the presence of stray capacitance across C , L and L' and the reflected impedance of L' into L .

I and *Q* Filters

The filter in the *Q* channel is shown in Fig. 11A. It consists of a single *m*-derived section and has a characteristic impedance of 1,000 ohms. The resistors shunted directly across the coils are employed for damping purposes to minimize ringing. An *m*-derived section ($m \cong 1.27$) is employed rather than a prototype section since the former provides a more nearly linear phase characteristic. This improved phase characteristic serves further to reduce ringing.

The *I* filter is of the form shown in Fig. 11B. It consists of a combination of tuned shunt peaking and series peaking. Both *I* and *Q* filters meet the NTSC specifications with a comfortable margin of safety. In both filters the residual ringing and overshoot is small enough to be negligible.

CROSS PULSE PICKUP

SUMMARY—To reduce bulk and expense in station layouts, engineers are often tempted to use twisted-pair cable instead of coaxial cable. Chart showing pickup in various kinds of cable indicates when this practice is acceptable

WHERE PULSED video signals must be connected to many different points in large electronic systems, the conservative approach is to use coaxial cables throughout. This ensures against cross pickup of signals between circuits, but can be expensive because of the cost of cable, terminations and installation labor. The bulk of the cable trunks can present problems in the layout of the system.

Tests on a sample length of twisted-pair communication cable and subsequent system experience have shown that certain types of pulsed signals, gate waveforms etc can be transmitted appreciable distances over twisted pairs without difficulty due to cross pickup. The feasibility of this method for a given application will depend on the steepness of pulses, sensitivity of other circuits to spurious interfering transients, length of cables etc.

It is important that the designer have some idea of the magnitude of the attenuation of cross pickup between pairs that can be expected under various conditions. The following information may help in deciding whether coaxial cable or twisted pairs can be used in a specific case.

A series of measurements was

By **J. GREGG STEPHENSON**

FIG. 1—Method for observing cross pickup in twisted pairs (A) and in single wires (B)

made on the cross pickup of pulses in a 100-foot length of standard, vinyl-jacketed, 26-pair communication cable, made with No. 22 solid copper wire with plastic insulation.

The connections for testing are shown in Fig. 1. Pair No. 25 was driven by a pulse generator with 10-microsecond pulses at 1,000 pps and 50 volts amplitude. The internal impedance of the generator was adjusted until the rise time of the pulse on the driven pair was 1 microsecond. Under these conditions the decay time was also found to be approximately 1 microsecond. The peak amplitude and nature of the transient on each of the other wires or pairs in the cable was then observed

and recorded on a wide-band oscilloscope.

Various impedance levels on the other wires or pairs were set by the value of resistors R. The attenuation data plotted in Fig. 2 were taken at the sending end of the cable, point A. Cable reflections complicate the nature of the transient observed at the far end of the cable, point B, but the general level of peak transients is about the same as that recorded at point A. The attenuation figures refer to the level of the observed peak of the transient due to cross pickup in decibels below the 50-volt input pulse on the driven pair. The attenuation figures actually represent a voltage ratio $20 \log_{10} 50/V_a$ where V_a is the peak voltage amplitude of the transient due to cross pickup. Strictly speaking, this is not in decibels because of the differing impedance levels.

Typical transients observed as a result of cross pickup are shown in Fig. 3.

Conclusions

The measured results lead to the following conclusions, which apply specifically to a 100-foot length of standard communication cable.

(1) With no grounded wires

IN TWISTED-PAIR CABLE

FIG. 2—Attenuation versus serial number of pairs in Alpha 1312 cable 100 ft long with 26 pairs of No. 22 solid wire; 50-v input pulse is applied to pair No. 25

in the cable, the cross pickup on individual wires of the other pairs is attenuated only 3 to 6 db.

(2) With no grounded wires in the cable, the cross pickup on individual wires of the other pairs improves to a level between 16 and 44 db when the impedance level is reduced to 100 ohms.

(3) Using twisted pairs, with one wire of each twisted pair grounded and serving as a partial shield, the attenuation of cross pickup increases markedly. At a 5,000-ohm impedance level, twisting improves the attenuation by 10 to 48 db. At a 100-ohm impedance level, twisting increases the attenuation by 9 to 26 db.

(4) The best conditions for attenuation of cross pickup were observed at a 100-ohm impedance level with twisted pairs.

The total attenuation varied from 24 to 68 db on various pairs. At a 5,000-ohm impedance level with twisted pairs, the attenuation varied from 13 to 54 db.

(5) The worst cases of cross pickup were observed on the

pairs physically nearest to the driven pair in the cable lay (pairs 9 and 11). The really bad cases appear to be limited to about 10 percent of the pairs in the cable. All others show at least 10 db more attenuation than the few worst pairs.

FIG. 3—Typical transients: 50-v input pulse (A), pickup at 5,000-ohm level, single wire (B), 5,000-ohm level, twisted pair (C), 5,000-ohm level, single wire at unterminated end (D), 100-ohm level, single wire (E) and 100-ohm level, twisted pair (F)

DESIGNING OVERSTAGGERED DOUBLETS

SUMMARY—Stagger-tuned amplifiers can be peaked to give response curves similar to overcoupled transformers. Advantages include increased gain and skirt selectivity. Curves provide a useful aid in designing the tuned circuits

By HAROLD D. WEBB

FIG. 1—Staggered doublet

DESIGN PROBLEMS

To select components for an overstaggered doublet, the designer must first determine the Q and resonant frequency of each tuned circuit. He begins by knowing only the desired center frequency, f_o , bandwidth B and permissible dip in db d .

The Q 's are to be equal for both tuned circuits. The resonant frequencies are related by α . If the frequencies are f_{o1} and f_{o2}

$$f_{o1} = f_o/\alpha$$

$$f_{o2} = f_o\alpha$$

Should the designer want to work from equations, he would determine first the quantity γ

$$d = 20 \log_{10} [1/\sqrt{1 - (\gamma^2 - 1)^2}]$$

from which $\gamma^2 - 1$ must be negative for overstaggering. This quantity is used to solve for q

$$q = 1/b \sqrt{(1 - \gamma^2) + \sqrt{1 - (\gamma^2 - 1)^2}}$$

where b is defined by $b = f_o/B$.

The designer may now evaluate the Q of the tuned circuits

$$Q^2 = [4 + q^2 + \sqrt{(4 + q^2)^2 - 8q^2\gamma^2}]/4q^2\gamma^2$$

Now α is found in terms of Q , q and γ

$$\alpha^2 = q^2\gamma^2Q^2 - 1 + \sqrt{(q^2\gamma^2Q^2 - 1)^2 - 1}$$

THE OVERSTAGGERED doublet gives an amplitude response with a dip resembling that for an overcoupled transformer. Its advantages include increased peak and center-frequency gain, increased skirt selectivity and less critical adjustment. The desired type of output can be obtained only in the absence of regeneration or any other type of feedback that affects the shape of the response characteristic. A staggered doublet is shown in Fig. 1.

Curve family I shows Q plotted against b for various values of dip d . Curve II plots a versus b . Quantity b is the ratio of center frequency to half-power bandwidth, and a is used to find the resonant frequencies. The values of a versus b are so nearly the same for various amounts of dip that only one curve for a versus b is given. This is the curve for the maximally flat case, $d = 0$. Also plotted are γ^2 versus d , curve III; peak gain improvement in db versus d , curve IV; center-frequency gain improvement in db versus d , curve V; and skirt selectivity versus d , curve VI. Skirt selectivity is the ratio of bandwidth 10 db down to bandwidth 3 db down.

From curves I the value of Q

may be read directly. The stage resonant frequencies are found using the value of a read from curve II. For a given value of C , L is found from $L = 1/C\omega^2$ and R is found for each stage from $R = Q/C\omega$.

For the curves the value of b is limited between 0.5 and 10. When the value of b is too large to be represented on the graph, find Q for $b = 8$, divide this value by 8 and multiply the result by the given value of b . To find f_{o1} and f_{o2} for values of b greater than 10 use $f_{o1} = f_o - B/2\sqrt{2}$ and $f_{o2} = f_o + B/2\sqrt{2}$; B is half-power bandwidth.

Example

Design a staggered doublet with center frequency 20 mc, bandwidth 5 mc at the half-power points and 1-db dip. Let C_1 and C_2 , the total shunt capacitances for each stage of the doublet, each be 12 μmf .

First, $b = f_o/B = 20/5 = 4$. From the 1-db dip curve I for $b = 4$, $Q = 8.9$.

From curve II for $b = 4$, $a = 1.093$. The center frequencies are $f_{o1} = f_o/a = 20/1.093 = 18.3$ mc and $f_{o2} = \alpha f_o = 21.9$ mc.

Two stages are used having center frequencies of 18.3 and 21.9 mc and effective Q's of 8.9.

The effective parallel resistance for the stage at 18.3 mc is $R_1 = Q/C_1\omega_{01} = 6,450$ ohms and for the stage at 21.9 mc $R_2 = Q/C_2\omega_{02} = 5,390$ ohms. The inductances are $L_1 = 1/C_1\omega_{01}^2 = 6.3 \times 10^{-6}$ henrys and $L_2 = 1/C_2\omega_{02}^2 = 4.4 \times 10^{-6}$ henrys.

The gain at the center frequency is $G = g_m/2\pi CB$, and the gain at the peaks is 1 db greater. From curves IV and V the peak and center-frequency gain improvements over a maximally flat stage are 3.6 and 2.6 db. The 10-db-down to 3-db-down skirt selectivity from curve VI is 1.52.

An alternate method is to determine Q from the 0-db-dip curve I, from which $Q_0 = 5.7$ for $b = 4$, and multiply this Q by the Q ratio obtained from curve VII for $d = 1$ db, which is 1.57. The Q used in the design is then $5.7 \times 1.57 = 8.95$.

Cascaded Pairs

In the design of overstaggered pairs for wide bandwidth response it is frequently necessary to use more than two stages. It may be desired to use two or more overstaggered pairs that are alike in design rather than to use a staggered quadruplet or sextuplet. The designer will be concerned with the overall bandwidth 3 db down from the peaks as compared to the bandwidth 3 db down from the peaks for one staggered pair. This information can be read from curve VIII, which is the ratio of the bandwidth 3 db down from the peaks to that of one pair versus d for various values of n where n is the number of like pairs that are cascaded. For n cascaded pairs the db dip for the overall response is n times the dip for one pair, if the pairs are all alike.

CHARACTERISTICS OF COMPUTERS

SUMMARY—Results of survey of digital computer manufacturers gives technical specifications on 32 computers with data on their associated magnetic-drum, tape and electrostatic-tube storage systems

NOTCH NETWORK DESIGN

SUMMARY—Charts and simple synthesis procedure speed determination of component values for loaded bridged-tee network operating between equal impedances, for any desired notch depth and frequency. Attenuation and phase response are also given

By G. J. SAVANT, Jr. and G. A. SAVANT

SERVOMECHANISM design and equalization often call for amplitude attenuation at a particular frequency. This requirement, as with noise filters and many other applications, can often be satisfied by use of a bridged-tee notch network.

Practically, these requirements are usually reduced to approximately a ten-to-one ratio of load impedance to network and driver impedance. But even this simplification cannot be accomplished in many cases without undue circuit complexity.

Design of the R-C bridged-tee network in Fig. 1 involves specifying the notch frequency ω_0 , the notch depth ρ expressed as the gain of the network at the notch frequency, the source impedance Z_A and the load impedance Z_B .

The parameter for notch width n need not be considered in the

synthesis procedure presented here because notch width is minimized.

In this design procedure the source and load impedances are taken to be equal. This advantageous choice permits the cascading of a number of networks all of the same impedance level.

Design Procedure

As the first step, enter Fig. 1 with the notch depth ρ and read the values of $C_1R\omega_0$ and $C_2R\omega_0$. Now set $R_1 = R_2 = Z_A = Z_B = R$ and calculate C_1 and C_2 . If necessary, the source impedance can be made equal to the load impedance by padding.

Example: $Z_A = Z_B = 100,000$ ohms, $\rho = 0.05$ and $f_0 = 20$ cps. From Fig. 1, $C_1R\omega_0 = 0.33$ and $C_2R\omega_0 = 3.0$. Now $Z_A = Z_B = R_1 = R_2 = 100,000$ ohms, $\omega_0 = 6.28 \times 20 = 125.6$ radians per sec, $C_1 = 0.33/100,000 \times 125.6 = 0.026$

μf and $C_2 = 3/100,000 \times 125.6 = 0.24 \mu\text{f}$.

The attenuation and phase response for the bridged-tee network of Fig. 1 are plotted in Fig. 2 and 3 as a function of the normalized frequency $\mu = \omega/\omega_0$. The amplitude curves have the same symmetrical appearance and form as in the unloaded case¹ with two exceptions: (1) The d-c and infinite frequency gain is $\frac{1}{4}$. This means that the network acts as a four-to-one voltage divider at any frequency; (2) the minimum notch width becomes excessively wide for values of ρ over 0.025. The characteristics invert for values of ρ greater than 0.25 and the notch network changes from a band-reject to a band-pass filter.

TRANSISTOR CHARACTERISTICS FOR CIRCUIT DESIGNERS

SUMMARY — Tables indicate physical properties, maximum electrical ratings, small-signal low-frequency parameters and average characteristics for grounded-base, grounded-emitter, grounded-collector and switching circuits for 218 transistor types: 106 junction triodes, 46 high-frequency triodes, 6 tetrodes, 23 high-power units, 25 point-contact and 12 phototransistors

SUCCESSFUL transistor circuit design requires not only familiarity with transistor equivalent circuits and characteristic curves but also an understanding of the behavior of the parameters describing the transistor and the variation of these parameters with bias and temperature. Tables I to VI have been compiled as a systematic presentation of data necessary for transistor circuit design.

Each of the charts presents physical properties, maximum electrical

By **SEYMOUR SCHWARTZ**

ratings, typical small-signal low-frequency parameters, average characteristics for grounded-emitter, grounded-base and grounded-collector circuits and switching characteristics. Figure 2 illustrates the circuits referenced in Tables II and III.

Small-signal parameters are expressed as resistances. This permits a familiar physical representation of the transistor in circuit design. Box on p R-59 enables transformation between h and r parameters.

All the characteristics are for fixed-bias conditions. However, these values vary with operating conditions. Examples of these variations are shown in Fig. 1A, 1B, 1C and 1D.

Figure 1A illustrates how collector capacitance C_c varies with collector voltage V_c . In designing an i-f tuned circuit, the tuning capacitor must be large enough to swamp out the effects of the variation of collector capacitance. If the i-f stage is a grounded-emitter rather than a grounded-base stage, the collector capacitance is magnified by the base-current amplification factor, β .

In i-f stages where neutralization is used to maximize gain by balancing out C_c , instability may occur when the battery voltage decreases.

This variation of C_c with V_c permits use of the transistor as a reactance element in i-m applications.

At low current bias, Fig. 1B, 1C and 1D, the noise factor of the transistor decreases and emitter resistance r_e , base resistance r_b , and collector resistance r_c increase, providing increased power gain and larger values of input and output impedance. This is advantageous in hearing aids where low bias currents are used.

Temperature Effects

In the germanium transistor, noticeable changes in α , β and I_{co} take place at approximately 60 C as shown in Fig. 1E. These changes can lead to instability at high temperatures by α becoming equal to or greater than unity or by I_{co} increasing and causing a collector runaway effect due to self heating.

Temperature problems are minimized in silicon transistors as seen in Fig. 1F. The value I_{co} becomes almost negligible in design consideration as the upper limit or temperature range is above 100 C. In such special applications as d-c amplifiers, the slightest change in α over the normal temperature operating range can produce a significant change in d-c current gain of the grounded-emitter stage.

The low-frequency low-power triode junction transistor, Table I, is most commonly used. The majority are utilized in hearing aids audio systems, low-power control systems

ABBREVIATIONS USED IN TABLES

α	Current gain
β	Base-current amplification factor
BW	Bandwidth
C_c	Collector capacitance
$f_{\alpha co}$	Alpha cutoff frequency
$g-b$	Grounded base
$g-c$	Grounded collector
$g-e$	Grounded emitter
I_b	Base current
I_{b2}	Second base current (tetrode)
I_c	Collector current
I_{co}	Collector cutoff current
I_e	Emitter current
I_{eo}	Emitter cutoff current
NF	Noise figure
r_b	Base resistance
r_c	Collector resistance
r_e	Emitter resistance
R_g	Generator resistance
R_i	Input resistance
R_L	Load resistance
R_o	Output resistance
V_c	Collector voltage

and low-speed computing circuits. Present units are available in the *pn*p and *np*n fused germanium, the *np*n grown germanium and *np*n grown silicon types. Of the fused type of transistor, the *pn*p is more available commercially and consequently has found a wider range of applications. The *np*n fused type is suitable for complementary symmetry circuitry. The grown silicon type is used for high temperature and low I_{co} applications.

The germanium and silicon grown transistors are used in almost the same manner as the fused transistor. Frequently, the grown types, owing to their lower value of collector capacitance and higher value of α cutoff, may be employed as

high frequency transistors.

The maximum power ratings on most of the low-power transistors

are of the order of 50 milliwatts collector dissipation at room temperature. Some of these units have

external heat sinks and are able to dissipate considerably more power.

The rating most commonly em-

imum current is selected where β has not decreased to too low a value.

Table II, high-frequency transistors, includes *pnp* and *npn* fused junction, *npn* grown junction and *pnp* surface-barrier units. Except for the *npn* grown type, which is of either germanium or silicon, all of these units use germanium.

Physically, one of the main distinctions between these units and the low-frequency units is the closer spacing between emitter and collector junctions. Electrical characteristics are higher alpha cutoff, lower collector voltage breakdown and in many units lower collector capacitance and lower base resistance. The widest application is in radio receivers and high-speed switching circuits.

In selecting a high-frequency transistor for a grounded emitter i-f amplifier, note that the β cutoff frequency of the amplifier is equal

to a cutoff frequency divided by β .

Table III lists tetrode junction transistors which are high-frequency triode *npn* grown junction transistors with an extra base lead and a narrower base region. The electrical characteristics of the grown tetrode transistor are almost identical to the grown triode transistor except for a lower value of base resistance and higher value of α -cutoff frequency. The extra base lead makes the tetrode applicable in specialized control circuits and avc applications. Bias for the extra base lead is usually obtained from a bleeder across the main supply.

High-Power Units

The high-power transistor, Table IV, is in most cases the largest of all transistors. One element is attached to the container. In most units the case may be connected to the chassis either directly or

Parameters			Typical Operation

² Socket type A to H

through a thin mica spacer. The types used as power transistors are the germanium *pn*p fused and silicon *npn* grown.

The *pn*p fused transistors are usually the high-power units whose larger physical size provides collector power dissipation up to 20

watts. The larger physical size also contributes a higher collector capacitance and lower α -cutoff frequency. Medium power *pn*p and *npn* fused units which retain their smaller physical size and most of the electrical characteristics of the low-power transistors are used

in applications requiring collector power dissipation below 1/2 watt.

The characteristics peculiar to the high-power transistor are the lower values of input resistance, output resistance and α , resulting from the higher values of bias currents employed. Bias stability tech-

FIG. 1—Variation of transistor parameters with operating point (A to D) and ambient temperature (E, F)

niques are used to minimize the effect of runaway due to self-heating of the collector.

The point-contact transistor, Table V, is limited to high-speed switching circuitry. Phototransistor devices, Table VI, are divided into two basic types: the two-lead and

three-lead devices. In the two-lead unit, one lead is attached to the base and the other to the collector. The three-lead device has leads going to the emitter, base and collector respectively.

The two-lead device is used in circuits providing d-c amplification

for unmodulated light while the three-lead device can be used in circuits employing a-c amplification for modulated light.

Acknowledgment is given to Ann M. Field and Elizabeth A. Sewell for their assistance in compiling data.

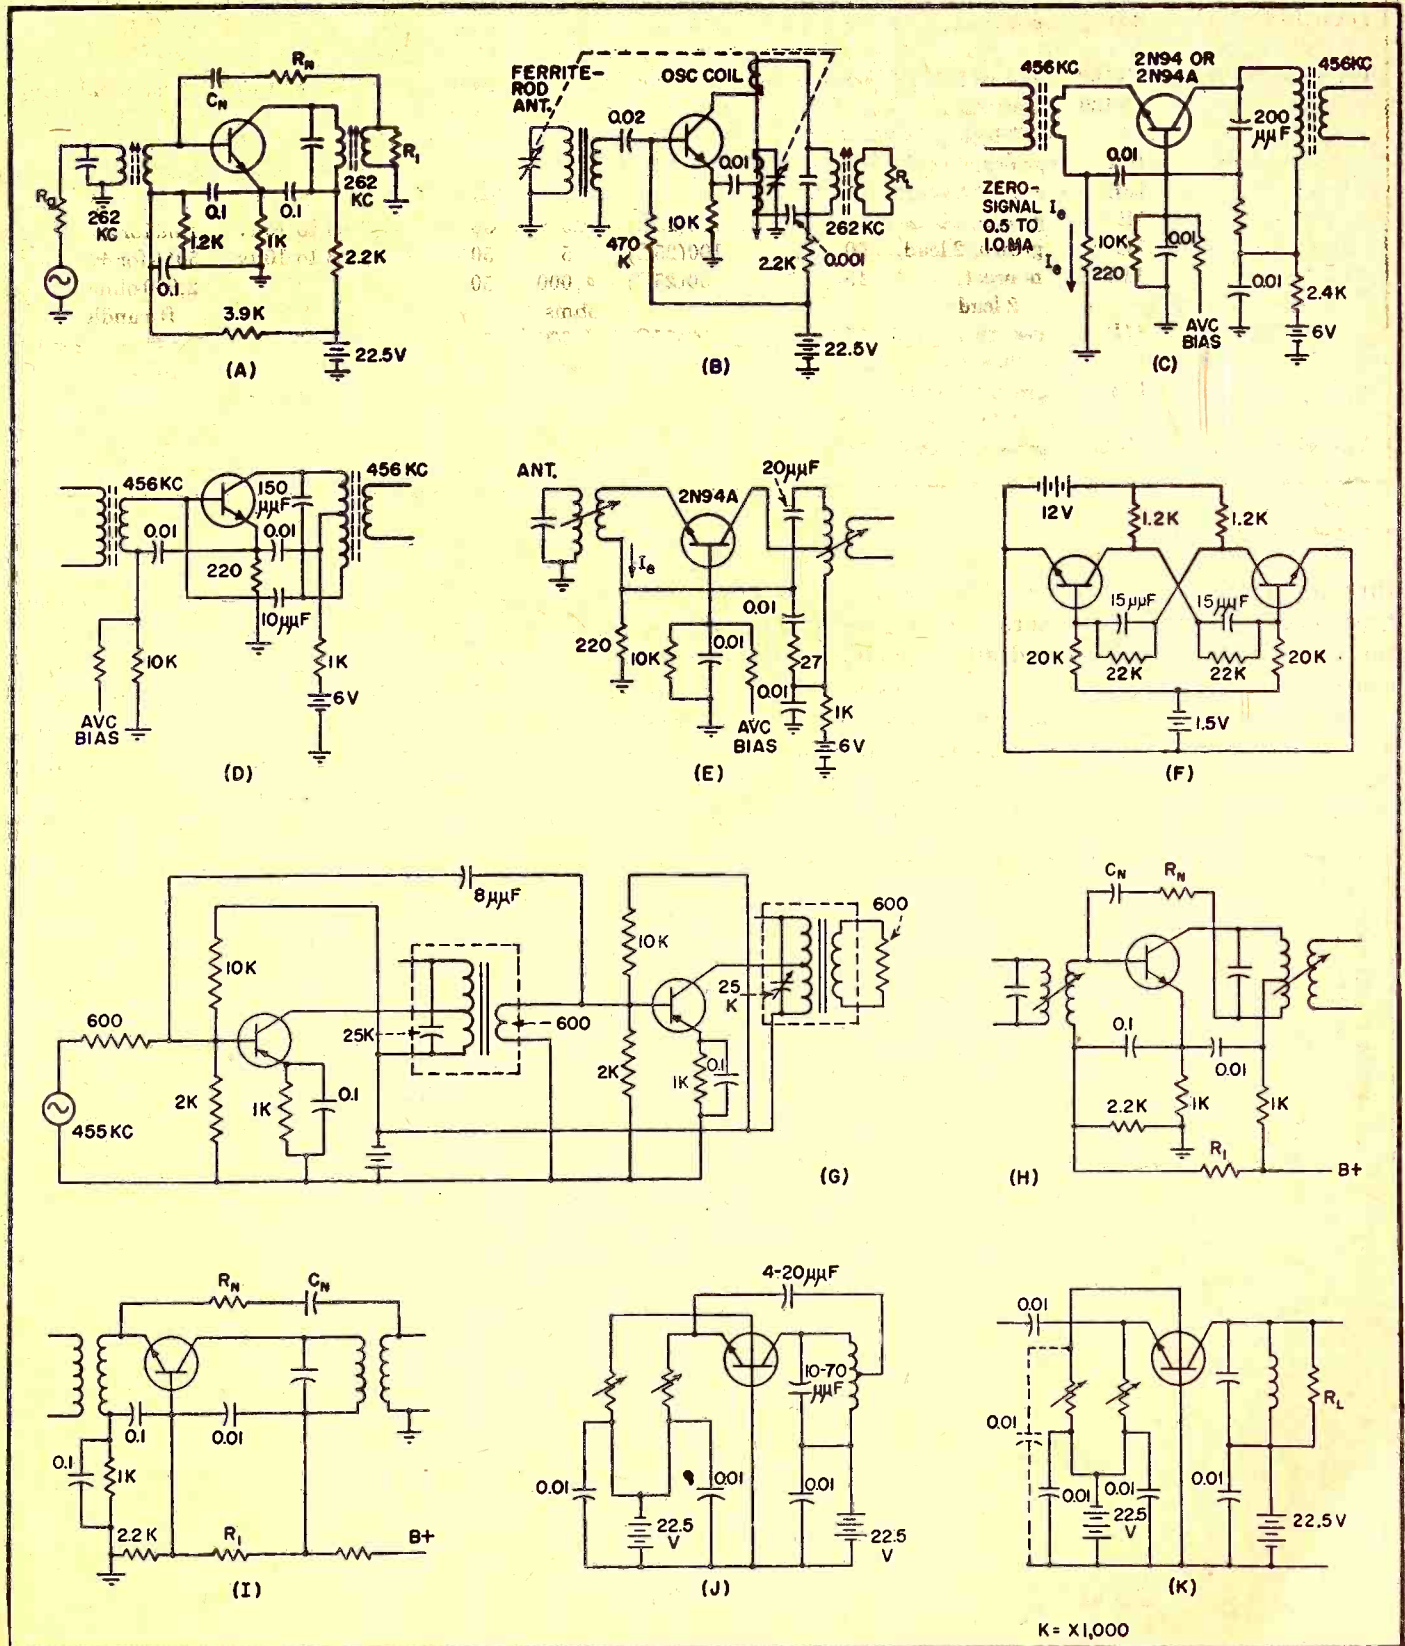

FIG. 2—Typical circuits for high-frequency transistors (A to I) and junction tetrode transistors (J, K) referred to in Tables II and III

STANDARD SYMBOLS

SUMMARY—Further simplification speeds drafting and cuts costs. Simple half-circles are now favored for coils. Basic switch loses arrowhead. Metallic rectifier symbol now serves for crystal diodes. Antenna goes back to triangle. Many microwave, transistor and photocell symbols appear here for first time

MOST-USED schematic symbols for electronic components are collected here on three pages for convenient reference, as abstracted from the new 54-page American Standards Association publication Y32.2-1954, "Graphical Symbols for

Electrical Diagrams" and (for transistors) from MIL-STD-15A, "Military Standard Electrical and Electronic Symbols".

Symbols may have any orientation, size and line weight. The open-circle terminal symbol may be added to leads if desired. Ar-

rowheads may be either filled or open unless otherwise noted. Electrically actuated devices are normally shown in the power-off position. One-line symbolism has been adopted for waveguide diagrams, as indicated for microwave symbols.—J.M.

product listings

O F T H E 1 9 5 6 - 1 9 5 7

electronics

B U Y E R S ' G U I D E

In the preparation of **ELECTRONICS BUYERS' GUIDE**, every effort was made to insure the completeness and accuracy of the Product Listings according to the information provided by the manufacturers.

The listings were compiled from information provided by more than 3,000 companies manufacturing electronic or allied products and include all products that will be available in the coming year, insofar as the companies themselves can determine. The completeness and accuracy of the listings are entirely due to the helpful cooperation of these manufacturers.

Products are arranged and indexed in a simple, easy-to-find, telephone-book style. Names of Manufacturers who are advertisers in the **BUYERS' GUIDE** are bold-faced in the listings and page numbers of their advertisements are shown. This makes it possible to obtain complete information on products quickly and easily by referring to the advertising pages.

Several new product headings have been added. Due to lack of sufficient information, only manufacturers who were known are included under these new headings. Listings include an index of registered trade names and an alphabetical listing of all companies engaged in the manufacture of electronic components, complete equipment or allied products.

NOTE: *This punch-out tab is for your convenience in locating the Product Listings in this issue. Simply push out and fold under. It will then serve as a tab mark to indicate where the listings start.*

PUSH OUT
AND FOLD

Alphabetical Listings Of All COMPONENTS—COMPLETE UNITS—ALLIED PRODUCTS Used in Electronic Equipment for All Purposes

The complete electronic and allied product lines of more than three thousand manufacturers are arranged and indexed in a simple, easy-to-use, telephone book style in the following listings.

Products are listed alphabetically by generic names followed by descriptive or type names where necessary, as **ADAPTERS—Battery**.

For example: To find the manufacturers of ionization tubes you would turn to the generic product heading **TUBES** and listed alphabetically under that you would find **TUBES—Ionization**.

The only exceptions are **INSULATING COMPOUNDS; INSULATION MATERIALS; INSULATION PARTS; METALS; PLASTIC MATERIALS; and TUBE PARTS**. Products falling in these classifications are arranged alphabetically under those six headings. A breakdown of electrical measuring

instruments is listed under the generic product heading **INSTRUMENTS, ELECTRICAL MEASURING** and cross-indexed. The same holds true for **MICROWAVE ACCESSORIES**.

Cross references are provided wherever necessary to cover names, other than the standard ones, that are sometimes used.

Manufacturers under each product heading are also arranged alphabetically. Those companies who are advertisers in this issue are bold-faced and the page numbers of their advertisements given to permit quick and easy reference for the necessary technical data.

In compiling the listings for this year's **ELECTRONICS BUYERS' GUIDE** extreme care has been taken to ascertain those products which are in production, or available within a reasonable time and, unrestricted for general industrial use.
