NHK Shines During Emergencies

by Thomas Caldwell

TOKYO

Like most nationally owned broadcast networks, Japan's NHK is set up to inform the public in the event of a regional or national emergency — be it an earthquake, flood, volcanic eruption or any of a number of catastrophes Japan is known to experience from time to time.

The January 17th earthquake centered around the port city of Kobe measuring 7.2 on the Richter Scale was just such an emergency. More than 5,000 people were killed by the pre-dawn quake.

FIRST REPORTS

NHK was the first with the news immediately after it happened and for the first several days following the quake. The speed in which NHK broadcast the data of the disaster within seconds of it happening was

almost as much a news story as the earthquake itself.

The system developed by NHK is probably one of the most extensive of its kind for covering natural disasters — but it is also very simple in design. The equipment used is not so out of the ordinary.

NHK has a network of 54 stations throughout Japan. Each one is tied to the other through a combination of leased circuits — both land line and satellite. Each of these stations is also connected to a local system of what NHK calls Skip-Back Recording Cameras. These units are placed at strategic locations throughout the country: city centers, airports, shipping facilities, train stations and other similar places. A camera is also located atop every NHK broadcast facility.

There are more than 100 cameras tied into the NHK network at any given time. Virtually every major landmark of the country is constantly being watched just in case "something happens."

When something did in Kobe, a Skip-Back caught the action of an NHK employee on night duty being shaken around the Kobe control room. Another atop the building captured the city lights shaking wildly and then going out.

The Skip-Back gets its name from the timing functions the camera has. All the cameras are on a delay action recording loop. That way, there is no chance for the people in the control room missing any of the action if the camera's image is not up on screen. The camera on the wall of NHK's

NAB 1995:
The MGM Grand Hotel is one of the many sights to see when the National Association of Broadcasters returns to Las Vegas.
For details, turn to page 19.

Kobe control room had a 10-second delay. Others have more or less delay depending on the location and camera type. When the earthquake alarm went off, the Osaka and Tokyo broadcast centers saw images within ten seconds, missing none of the action. The worst of the quake lasted only 20 seconds.

The cameras vary in size and design. Some are Hi-8 and others are full broadcast cameras. Not all of the cameras are on at all times. Most of them, like the one in the

Kobe control room, are activated automatically under certain circumstances, such as earthquakes.

EARLY WARNING

As far as earthquakes go, NHK's computers are tied directly into the earthquake warning and notification system at the government's Meteorological Agency — the part of the government responsible for measuring earthquakes. The system consists

Save Your PC Animation From Being Eaten Alive.

You know how an animation can take on a life of its own. Sometimes it takes forever. Or it costs too much. Or a tape machine mistakes it for lunch.

The DPS Personal Animation Recorder™ solves these and other animation-production problems. The IBM PC® compatible DPS Personal Animation Recorder complements all 3-D applications which generate 24-bit image files, including 3D Studio® and TOPAS Professional.™

With the DPS PAR,™ you can digitally record your animations onto a dedicated hard drive* and play them back in real time. Which means you can create 3-D animation without the expense and aggravation of single frame tape decks.

Because the Personal Animation Recorder operates in a totally digital environment, you

can master an infinite number of first-generation tape copies. Component (Betacam®, MII®), S-Video (Hi8®/S-VHS) and composite video outputs are standard. For rotoscoping, just add a DPS Video Capture Card which allows you to capture real-time video on the PAR's hard drive.

Rescue your productions from the jaws of traditional animation systems for a fraction of the cost with the DPS Personal Animation Recorder.

NEW ASTRA BIRDS COMMISSIONED

LUXEMBOURG

The Société Européenne des Satellites (SES) has commissioned a seventh satellite, designated 1G, with the Hughes Corporation and placed an option for its successor, Astra 1H.

The new satellite is due to be launched in the Spring of 1997 and is to be co-positioned with all other Astra satellites in geostationary orbit at 19.2 degrees East for Europe. This is SES's seventh and the third that is to be digital. Astras 1E through to 1G are to use the so-called high band (11.7 to 12.75 GHz) and will provide Europe with a total of 57 digital transponders, each capable of transmitting some ten channels using MPEG compression.

Astra 1G and 1H are to be Hughes 601 High-Power series birds producing a TWT output of 100 watts with an EIRP of 52 dBw. The life expectancy in stable orbit is 15 years and total power consumption 7.075 Kw. Astra 1G is to have 56 transponders on board, but only 16 are to be used for primary transmission, the other 40 to be used for backup for Astras 1E and 1F.

The newly commissioned satellites are to have a new antenna design made of two ultra-light reflectors using what Hughes calls "Contoured Surface Technology." The launch vehicle has yet to be decided.

Meanwhile, Astra 1E is to be launched with Ariane flight number 78 this year, and 1F is to go into space on the Russian Proton D-1-a rocket. The Russian vehicle is from the LKIE consortium, a joint venture between Lockheed Corp. of the U.S., and Khrunichev and NPO Energia, both of Moscow.

CABLE

JAPANESE CABLE SYSTEMS PLANNED

TOKYO

A group of Japanese and American companies have agreed to form a new company that will establish cable television systems in Japan.

The company, to be called TITUS, will be owned by Itochu Corp., Toshiba (28.4 percent each), U.S. cable television systems owner Time Warner (15.4 percent) and U.S. telephone company U.S. West (17.9 percent). In addition, a Time Warner Subsidiary, Time Warner Entertainment, which is part-owned by U.S. West and several Japanese investors, will own 9.9 percent of TITUS.

The company is funded with US\$28 million in start-up capital and will be headed by Minoru Akimora, formerly an executive at Itochu.

Initially, the company plans to create three cable systems in the Tokyo area serving about 700,000 people. However, the company expects to add additional systems with a total subscribership of about 2 million.

The company was formed largely in response to new cable/telephony guidelines issued on November 8. In addition, the government has said it will provide low-cost loans for cable development.

NETWORKS

SINGAPORE PLANS VOD TRIAL

SINGAPORE

Singapore Telecom (ST), the nation's telephone service, has announced it will conduct a video-on-demand (VOD) using video server technology from Hewlett-Packard.

The trial, announced under the government's IT 2000 communications initiative, will provide a portion of ST's 3.2 million customers with interactive programming, home shopping and other services. The heart of the system will be Hewlett-Packard's MediaStream video server which is capable of delivering from 75 to 10,000 separate video streams.

Other companies involved in the project are Mitsui & Co. and Fujitsu Ltd. of Japan, Philips Singapore Pte Ltd of the Netherlands, and Sybase Inc. of the U.S.

MULTIMEDIA

FIRMS EYE GERMAN MARKET

STUTTGART

With a plan to establish a fiber optic-based interactive video system dashed by the European Commission, two leading media companies are attempting to set up a similar program with Daimler Benz.

Late last year, officials from the Leo Kirch media group and the Bertelsmann chairman Mark Woessner met with Benz chairman Edzard Reuter and his appointed replacement, Jurgen Schremp. Also at the meeting was publisher Burda Verlag, a leading investor in the Europe Online video network project. The object of the meeting was to outline how to install a "video-on-the-internet" type of multimedia company that would use fiber-to-the-home technology to deliver programming to the German market.

The drive to establish such a network is largely fueled by developments in the U.S. Continental Cablevision in Boston, Massachusetts, for one, is working to provide residents of Cambridge, Mass., with broadband Internet access. Also Jones Intercable of Englewood, Colorado, has already begun offering broadband Internet in Alexandria, Virginia, and perhaps most significantly, Viacom is setting up a trial system in New York.

In Europe, operators claim that regulations and the continuing state monopolies in most mainland countries prevent the development of similar services. The U.K. has granted a license to TeleWest Communications to start a pilot scheme in London, and Nynex CableComms is planning a broadband Internet access system in Manchester. But in Germany, Deutsche Telekom is lobbying hard to be allowed to keep its monopoly

until the EU 1998 deadline.

Daimler Benz, parent company to Mercedes Benz, Deutsche Aerospace and AEG, already has its own world-wide satellite and fiber network. Schremp has stated that the company intends to enter the broadband multimedia market using knowledge already gained from its own operations.

Meanwhile, the German electrical supply company Veba has applied to the government to be allowed to install fiber to the home. A spokesman for Veba said that talks between Veba chairman Ulrich Hartmann and Bertelsmann's Mark Woessner had already taken place.

Late last year, the European Commission rejected a plan by Bertelsmann and Kirch to establish a broadband service with Deutsche Telekom.

SATELLITE

APSTAR-2 LOSS HURTS PROGRAMMERS

BEIJING

Video programmers were badly hurt by January's loss of the Apstar-2 satellite, which was destroyed during the explosion of a Chinese Long March rocket.

The satellite, a Hughes HS-601 bird, would have provided 26 C-band and 8 Ku-band transponders for delivery of video, telecom and data throughout much of Asia, Eastern Europe, Africa and Australia.

Among the programmers that were slated for service were Capital Cities/ABC, Discovery, ESPN, HBO, Reuters, Turner and Viacom.

As of presstime, companies were reported to be looking for carriage on NASA's Tracking & Data Relay satellite or possibly PanAmSat's PAS-2 bird.

Meanwhile, Beijing officials announced that six people were killed and 23 people were injured from falling debris from the rocket, which exploded shortly after launch on January 26. As of presstime, there was no explanation for the explosion.

APT Satellite Co., the Hong Kong-based owner of the satellite, has vowed to launch a replacement as soon as possible.

COMPRESSION

ALCATEL, NUKO OFFER NEW MPEG 2 SERVICES

RICHARDSON, TEXAS

Alcatel Network Systems and NUKO Information Systems have reached an agreement to provide a new line of MPEG 2-based services to cable headends and satellite providers over existing telephone networks.

The services will be available through Alcatel's Switched Digital Video Network (SDVN) and will take advantage of NUKO's MPEG 2 codecs and Alcatel's 1000 AX ATM system.

The Alcatel SDVN network is currently operating under the Cinema of the Future network form U.S. telecom Pacific Bell. The network provides high definition movies to theaters over fiber optic lines.

The new MPEG 2 services are expected to go to trial in the United States early this year.

Choose Compression Carefully

by Lynn Chroust

GUEST COMMENTARY

OPINION

Today, video servers are offered with a variety of methods to store digitized video, from uncompressed to JPEG to MPEG with hybrids in between.

Obviously, picture quality is a main concern in choosing a video server, but there are a number of other factors that should be considered when evaluating different manufacturers' equipment. What will my choice of compression allow me to do? What won't it allow me to do? What are the trade-offs of different compression schemes? What is the most effective way to evaluate different manufacturers' claims regarding picture quality?

THE RIGHT WAY

Many companies are making claims about the "right" compression for broadcast applications. However, the truth is there is no right method, and even servers that leave the choice of compression to the user have their limitations.

Obviously, one of the biggest concerns in choosing a video server is the video quality. None of us want any surprises when airing a high-profile commercial from a major advertiser. Why, then, use compression at all in a broadcast video server? The simple

reason is cost. One 30-second commercial in an uncompressed format (CCIR-601) requires a little over one gigabyte (GB) of storage. Multiply that by an average commercial library of 300 to 400 spots and the cost of storage alone is tremendous. And while prices are falling rapidly (dropping by half every 18 months), waiting until you can afford an uncompressed video server probably is not justified given the benefits of improved efficiency and reduced costs you can reap today.

Based on economics, most people concede that compression is required. Now, the choice comes to the type of compression to use: MPEG, JPEG, SPEG or one of the numerous other types that are available. How do you choose among these? Fortunately, the answer does not involve going back to school. Simply put, the best judge of picture quality is your eyes. Add a high-quality monitor and controlled lighting, and you have a good set of evaluation tools. Some of you may have been expecting a more objective, scientific answer. Unfortunately, at this time there is no objective method or test equipment to provide a clear answer. Your eyes are your best judge.

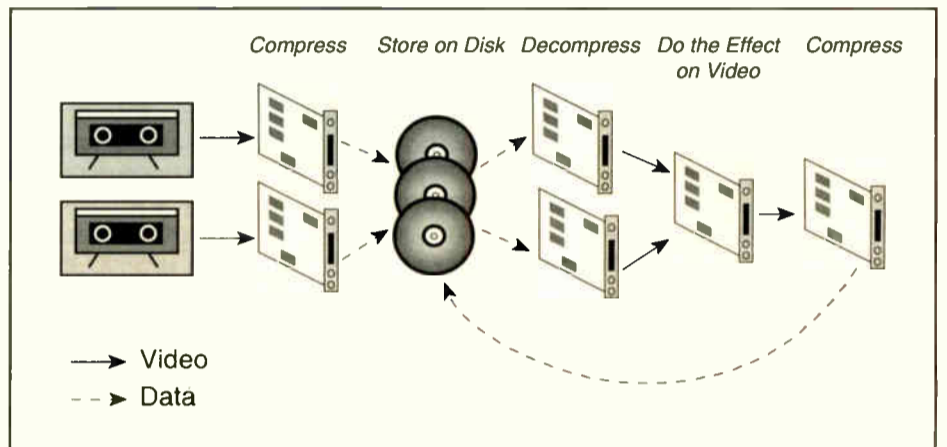

Some people may argue that the compression ratio is an accurate means to evaluate different servers. However, there is a fallacy to this method. Many compression methods can be varied, and a compression ratio is a measure of how much data has been removed. So, if the compression ratio of a picture is given as 2:1, then approximately half the information has been removed. However, this is not an indication of relative picture quality because the two servers may use different algorithms.

For instance, JPEG compresses video by removing redundant information within a frame, a process known as interframe compression. MPEG looks at a group of frames

and takes advantage of the redundant information within a frame and between frames, or intraframe compression. Because of the single fact that the compression algorithms are fundamentally different, compression ratio comparisons will not give you an indication of the relative picture quality of the two algorithms. It is like comparing apples and oranges. With even more compression schemes on the way, the safest way to protect yourself from a salesman's pitch is to use your eyes.

SIDE BY SIDE

A few words then about evaluating picture quality. While the trade show floor is an excellent time to see all vendors' systems in one place, it is not a good place to compare video quality. A reputable manu-

facturer should be willing to give you a tape of your material played through their system. Better yet, they should offer delivery of a system for evaluation in your own facility. But if a tape is all you can get, do the following simple tests. First, ensure that your tape has a variety of material on it, including fast motion, slow motion and graphics. Put the original and compressed material and the different compressed versions through a mixer and

do a split screen. A split screen is important because it eliminates your eyes jumping from monitor to monitor. It also will eliminate any discrepancies due to imbalanced monitors.

While picture quality is the ultimate test, there are other important factors to consider when evaluating compression algorithms. Three of the most important factors are storage efficiency, editability and transportability.

As mentioned above, video requires a significant amount of data, so storage costs are going to be a big part of the total system cost. The right choice in a compression algorithm can have a positive impact on your system cost. Currently, the two most common choices of compression are JPEG and MPEG. Because of the difference in interframe and intraframe compression, JPEG uses twice as much data as MPEG to get the same picture quality. To be specific,

the picture quality of a 24 megabit-per-second (Mbps) JPEG data stream is at least equivalent to a 12 Mbps MPEG stream, and depending on the type of material, MPEG may be even more efficient. Because JPEG is at least twice as storage-hungry as MPEG, you can store double the amount of video material if it is MPEG-compressed. This could definitely have a big impact on your budget.

So, why would anyone use JPEG? Because of the relatively low volumes in which they are manufactured, MPEG chips are currently more expensive. In fact, at today's MPEG chip cost, MPEG only becomes more economical than JPEG if you store six or more hours of video. However, major manufacturers IBM and LSI have announced MPEG chip sets for 1995 in the same price range as JPEG, so expect cost reductions to follow soon. Total storage needs over time, not just initial purchase requirements, should be factored into your decision.

EDITING CONCERNS

Another factor to consider when choosing a compression algorithm is how easy it is to edit video in its compressed form. Some claim that only JPEG is editable. This is untrue. The first step in any non-linear editor is to digitize the video. Coming in as full bandwidth video, it passes through a JPEG encoder and is stored in compressed format on hard disk. As a user drags and drops scenes together, an EDL (edit decision list) of these different scenes is created inside the editor. The compressed video on the hard disk is not modified or rearranged to line up in the way that the clip is being edited together. When the edited piece is played back, the non-linear editor follows the instructions on the EDL, and the hard disk streams off the compressed data in the correct order. The compressed data is fed through a JPEG decoder and is seen on a monitor. The video is seamless because the

Rainy days

Dear TV Technology:

The cover article on your December '94 issue of the International Edition of TV Technology entitled "Wireless Cable Coming on Strong" by Andrew von Gamm contains a few misconceptions we would like to correct.

The team from Sarah Clay & Partners Ltd. stated "One of the major difficulties facing MMDS is rain attenuation." We feel certain they were referring to the 12 GHz system Marconi installed in Hong Kong. We have been building 2 to 3 GHz MMDS systems around the world since 1984 and

have never encountered rain fades in this portion of the frequency spectrum, even in Panama where the rainfall can reach 10 inches in an hour. The quote would infer that all MMDS systems suffer from rain fades, and that simply is not true.

Regarding the fears of microwave radiation in Ireland, perhaps instead of eliminating the word "microwave" from the acronym as the British have done with the MVDS, we should look at the realities of radiation danger from MMDS.

The maximum allowable dosage of microwave radiation to the human body is 5 milliwatts per square centimeter. By Andrew Corporation's calculations, the 11-channel MMDS systems in Ireland produce an effective radiated power out of the transmitting antenna of 3,763 watts.

However, at 40 feet from the antenna, the actual microwave radiation is only 0.00079 milliwatts per square centimeter. Their household microwave oven probably gives them a heavier dosage than that. For the citizens of Ireland, the dosage would even be less than those given above, because we are almost certain no one lives within 40 feet of the transmitting antennas. Humanity loves to frighten itself with imagined dangers.

Jack A. Rickel
President/CEO
Comex Worldwide Corp.
1657 Northwest 79th Ave.
Miami, Fla., U.S.A. 33126-1105

Andrew von Gamm replies:

Mr. Rickel is correct in stating that rain attenuation at around 2 GHz is negligible. Unfortunately, use of this band is either limited or unavailable in most parts of Europe and the Far East. The figures for rain attenuation during a tropical down-pour (100 mm/hr) for horizontal polarization provided by Sarah Clay & Partners, Hong Kong, are:

- 2 GHz VMS/AM 0.05 dB/km
- 12 GHz VSB/AM 4.6 dB/km
- 12 GHz FM 4.6 dB/km
- 29 GHz FM 20 dB/km

The figures for vertical polarization are some 25 percent better.

In the second point, Mr. Rickel seeks to allay the fears of the European Green movement with rational argument. Having seen such films as "Godzilla Meets the Three-Headed Space Monster," German environmentalists have effectively banned all DNA research (much to the benefit of the U.S. and U.K. biophysics industry). There is now a movement throughout Germany to have mobile digital telephone banned on the grounds that we shall all get brain tumors. No matter how asinine an argument may be, if introduced before a technology has gotten off the ground, it has the effect of delaying its start and possibly killing it altogether.

**The new Sony
9-inch monitor.
It cuts out the need for
a D/A converter.**

It may seem like a minor issue.

But saving a small amount of space when that's all you have adds up to a big benefit.

Introducing our new digital 9-inch monitor. Because it has a built-in SDI interface, it cuts the need for a D/A converter.

And that means one less piece of kit in the OB van. One less piece of occupied space in the edit suite.

And wherever you are, a handy piece of space liberated for

some coffee and a hamburger.

There are also the small matters of Sony digital picture quality and Sony features – which you'll also find on our 14-inch SDI monitor.

But they're something we'd never dream of cutting.

The Sony BVM-9044D digital monitor. One less box, one more space.

And one cut that no-one's ever going to complain about.

SONY

CONTINUED FROM PAGE 6

Choose Compression Carefully

system is designed to be able to jump anywhere on the hard disk to play the compressed video without any glitches. In this cuts-only example, the JPEG video, as originally compressed, was never modified or moved on the hard disk. To add effects, the same process is used. However, the effect is created in full bandwidth video. So, the two streams are fed from the hard disk, decompressed, run through the effects device and the resulting effect is JPEG compressed and stored to hard disk. The new scene with the effect is inserted into the EDL and playback happens as in the cuts-only case.

So, what is the point of all this? The JPEG data was not magically edited. Clips are pasted together frame-accurately for cuts only and when effects are needed, the compressed video is brought back to full bandwidth, operated upon and then recompressed. The lesson is that today any compression algorithm when edited uses these same steps, including Wavelets and MPEG. A final argument used against MPEG is that while editing is possible, it is not on a frame-by-frame basis. Skeptics say that editing can only happen at the beginning of the group of frames, which is every 8 to 12 frames. This is also untrue, as evidenced by the Hewlett-Packard Broadcast Video Server, which is able to stop, start and join clips together at any time code frame accurately.

SHARING FILES

Besides picture quality, storage efficiency and editability, there is one other important attribute of compression algorithms that needs to be considered, and that is transportability. Transportability is a new concept that has not received a lot of discussion but could be the key in your ability to control costs and add new revenue-generating services to your facility.

Transportability is a characteristic of a

compression algorithm that allows it to be encoded and decoded with a standard key. This means that the compressed data can be decoded by a different manufacturer's device than the one that encoded it. With high-quality compressed video stored in network-accessible servers, the possibility of transferring video over high speed digital networks is a realistic alternative to the

opportunity to allow you to change the way you receive and distribute video, as digital networks become more prevalent and lower in cost.

Finally, there are servers that let you operate with both compressed and uncompressed video simultaneously, which would seem to be the best of both worlds. However, this capability also has limitations.

When examining a video server with this capability, you must always account for the highest bandwidth required if you

are to ensure sustained playback and record functions. For example, if you want the ability to play out uncompressed video for a small fraction of your library, in order to ensure this is always possible you must assume that the play-to-air channel is always uncompressed. Otherwise, when

designing a multichannel system, you may block your ability to record or play back on other channels because your system has run out of bandwidth. Similarly, if you want to dub in uncompressed video, then that channel must always be thought of as running uncompressed during system design. This will naturally lead to a more expensive system, as one uncompressed signal means your minimum system bandwidth is 270 Mbps. Simultaneous record and play of uncompressed video requires a system bandwidth of 540 Mbps, and so forth. If only a small fraction of your material needs to be compressed, it may be more economical to store those on tape or a long-form digital disk recorder.

The compression format used by a video server can have some serious consequences for your lifetime storage costs, as well as your ability to link into digital networks easily for delivery or receipt of video material. Carefully considering these factors as well as picture quality in a controlled environment is the key to achieving your business goals with a video server. ■

Lynn Chroust is product manager for broadcast video servers at Hewlett-Packard. For further information circle Reader Service 43.

Obviously, one of the biggest concerns in choosing a video server is the video quality.

physical method used today. The ability has been in existence for some time, but never at an economical cost. Given the high data rate of video and the speeds of existing networks, high quality compressed video uses significantly less bandwidth and allows fast digital networks to deliver information at faster than real-time speeds, improving the ability to deliver information in a timely manner. In fact, several leading edge broadcasters have adopted this means already as a way to save costs and improve response time and efficiency. In addition, a transportable compression format also means that the broadcast community will not be locked into using one manufacturer's equipment.

JPEG, while standardized in some respects, does not define a standard key allowing equipment of different manufacturers to work together. This is why non-linear editors cannot share compressed video files today. Each manufacturer has developed its own key, preventing interoperability. Today, only MPEG defines a standard key, or transport layer, allowing many manufacturers to make equipment that can operate together. MPEG offers the

CONTINUED FROM PAGE 1

NHK's Emergency System Shines

of a series of mini-computers tied together with a simple 4800 baud leased line.

The software packages running on the computers at the agency and NHK are identical. They effectively are one system. When an earthquake happens anywhere in the country, the agency's computer notifies the NHK system of the location and magnitude of the quake. This data is then sent to simple desktop PCs and processed into images that are

then transferred to screen and broadcast automatically.

To back up its data from the government, NHK also has its own private network of earthquake detectors at each of its stations. The data from these units are not broadcast on the air but are, according to NHK, used only for reference.

The system may sound rudimentary, but it is very fast. When the Hokaido area was hit by a major earthquake at the end of December, the news of the earthquake only took a few seconds to reach Tokyo, but the shock wave from the earthquake took one and a half minutes to reach the Japanese capitol. People were being told how powerful an earthquake was before they had even felt it.

Since the quake, NHK has gotten what a company spokesman called "several inquiries" from overseas governments interested in learning more about their emergency broadcast system. Officials from the company would not comment on whether or not NHK may help set up similar systems in other countries. One of the companies who would profit from any such export of this type of system would be the company that developed the Skip-Back recording system with NHK; Osaka-based Eletex Co. Ltd.

Because of its simple design, the NHK system could be easily duplicated elsewhere. It is a very good example of using simple, reliable equipment to get real "high-tech" results. Instead of looking for the most up-to-date equipment available, the engineers at NHK just made due with the best they had — and it worked. ■

Thomas Caldwell is a Tokyo-based writer and radio journalist. He covered the Kobe earthquake for Monitor Radio.

ARRI TV, Munchen.**

'At ARRI TV we produce and edit a lot of television programmes, like this one for SAT 1. *Riskier Was* is all about taking risks, but it's only a game – and if you lose, it costs you nothing.

'Real life isn't like that. A bad business decision can lead to disaster, so we thought long and hard about our upgrade path to component digital.

Digital BETACAM™

'In the end, only one format was good enough – Digital BETACAM from Sony. It gives us superb pictures in a value-for-money package. And for longer programmes, where the budget doesn't justify D-1, we get high quality at a realistic cost.

'We also use Digital Betacam in telecine. Because colour correction can take up a lot of expensive time, we do it all after recording onto Digital Betacam – and put the telecine to more profitable use.

'Something that's also particularly important to me is sound. As more programmes are transmitted in stereo and the sound handling of domestic receivers improves, audio quality becomes increasingly critical. Digital Betacam allows audio to stay in the digital domain, right through the production process – and produces a superb result.

'So for us, choosing Digital Betacam was never a risk. It was always a certainty.'

Glue lagoon

Just as a lagoon is separated from the ocean by reefs and sandbars, so your digital facility is separated from a sea of analogue signals.

Audio and Video Synchronisers

Synchronising signals with Leitch equipment brings a tranquility and peace of mind that we call 'Glue lagoon'. Performance is guaranteed by using innovative and proven technology to perform video

retiming functions or to stabilise the most turbulent audio and video feeds.

Therefore, should you require multiple synchronisers operated under a single powerful control system, synchronisation of audio to video or simple line synchroniser functions, Leitch offers the complete solutions.

With experience and understanding Leitch applies advanced technology to your applications, bringing the most effective solutions to modern broadcasting.

Call Leitch or your nearest dealer today.

Interactivity in the Here and Now

While Most Firms Are Talking a lot About Interactivity, Few Are Actually Delivering It

by James Careless

TORONTO

In North America, the hype surrounding the "information super-highway" is everywhere. Promises abound of broadband networks with virtually limitless capacity and set-top technology that will turn every household into an interactive multimedia showcase. And above all are the opportunities to make money, money, and more money.

Unfortunately, to date most of these promises are just that: promises with apparently no pay-off close at hand.

Still, there are a handful of systems ready for installation right now that provide interactivity, or at least the illusion of it.

UP AND RUNNING

For 230,000 subscribers in the province of Quebec, Canada, for example, two-way interactive television is not just a promise, it's a reality. For the past four years, cable company Videotron

Herbert said. "It's your choice."

In this regard, Videotron's "two-way interactivity" is actually simulated, as it is for users who download video games from the system.

However, the network is capable of allowing subscribers to perform other truly interactive tasks.

For instance, Videotron subscribers can send simple e-mail to other system users. They can also shop at home by selecting items off the screen via the remote control and paying for them using Videotron's credit/debit card reader. Merchants can also issue coupons to customers at home using the set-top printer. In addition, the data terminal can be configured as a high-speed modem for two-way PC data transmission via cable.

Most of all, what makes Videotron's Videotron broadband technology stand out is the simple fact that it has been up and running successfully for four years. Certainly the graphics it

Time Warner for a year now.

"Most of them are being installed and engineered for 750 MHz bandpass," said Robert Young, GI's director of distribution services. These networks provide "full channel loading for 80 (analog) channels and 200 MHz digital."

Scientific Atlanta is also emphasizing the importance of boosting broadband carriage capacity, said company spokesperson Bob Brobst.

"Without that added bandwidth, you do not have interactivity," Brobst said. "So we are laying the groundwork with all this 750 MHz architecture to have interactivity in terms of traditional games and shopping and all that, but also telephony."

The centerpiece of SA's broadband product strategy is its 8600X set-top converter, properly known as a "Home Communications Terminal" (HCT).

Like GI's CFT 2200, the 8600X's technology is analog, not digital. But despite this,

docking station. By offering this configuration, SA is making it possible for cable companies to upgrade their set-top boxes now, while DVC is just economically out of reach, without making the inevitable transition to digital unnecessarily costly.

The success of Videotron, General Instrument and Scientific Atlanta in rolling out commercial broadband products and services offers some hope to engineers in the television industry. While we are still a long way off from achieving the true potential of the information highway, the necessary technology is finally starting to become a reality. ■

To the user, it appears that Videoway is actively switching shots in response to remote control commands.

has been successfully installing its own in-house "Videoway" technology in subscribers' homes here, as well as selected territories in the U.S. and U.K.

In the home, Videoway consists of a set-top data terminal, a remote control unit and an optional peripheral unit capable of scanning credit and debit cards for on-screen purchases, plus a coupon printer for promotional offers.

For users, this equipment offers many features, the first being "interactive television." Using Videoway, viewers can select a hockey game, for example, and decide which of four camera shots they want to use to view the action, switching between them at will.

To the user, it appears that Videoway is actively switching shots in response to remote control commands. In reality, says Pierre Herbert, Videotron's senior vice president of marketing, the cable company is feeding four different live feeds to the set-top box via four separate channels. The remote control simply switches seamlessly from one to another on command.

In the same way, when watching the evening news, "you could end up watching international news, or sports news, or local news."

provides are not the most sophisticated, nor are many of Videoway's "interactive" functions. However, the system is available now, and it works.

BANDWIDTH RESTRICTIONS

When it comes to making the "information highway" a reality, one obstacle looms larger than all the rest: bandwidth. Audio/video digital transmission requires vast amounts of bandwidth, which is why companies such as General Instrument (GI) and Scientific Atlanta (SA) are concentrating on the equipment capable of providing it.

For instance, under the name "Broadband Telecommunications Architecture," GI is currently offering a complete end-to-end broadband system featuring the CFT 2200 set-top box. The system provides "full two-way interactivity," said Tom Lynch, GI's vice president of terrestrial distribution systems.

"Subscribers can compete against other subscribers with video games, talk to one other on the telephone or communicate with on-line services using their computers," Lynch said.

GI has been selling such systems to U.S. cable operators like Tele-Communications Inc. and

Brobst insists the 8600X is a truly interactive component. He says it is "a common misconception, that you need digital for any kind of interactivity."

In its current configuration, the 8600X offers a wide range of functions. In addition to handling both near-video-on-demand (NVOD) and pay-per-view (PPV), plus the ability to operate connected VCRs, the 8600X features an onboard electronic TV program guide.

This text-only guide "is not a passive scrolling device," Brobst said, but is "really interactive in terms of point and click," using the four-way directional arrows on the remote to move the cursor to choose selected items.

VIRTUAL CHANNELS

Another noteworthy feature is "virtual channels," a method of providing additional channels to subscribers without using any extra bandwidth. The 8600X does this by extracting data services, such as news, sports and weather, in which the signals have been "piggybacked" on the vertical blanking interval of existing channels. In this way, SA estimates that most cable systems can provide 100 or more virtual channels using the 8600X.

The Math Behind the Modulator

by Brian Flowers

ENGINEERING CORNER

The modem performs an important role in digital television satellite links. It transforms the baseband data signal into an IF (Intermediate Frequency) modulated carrier and vice versa. In addition, it introduces FEC (Forward Error Correction), it buffers the received signal to cope with the Doppler effect, and it recovers the clock reference.

Actually for TV signals, we should refer to modulators and demodulators separately, because TV signals are normally unidirectional. Telecommunication circuits, on the other hand, are invariably duplex, hence the derivation "modem" for a modulator/demodulator combination.

The Eurovision satellite network requires about twice as many demodulators as modulators, so each earthstation can be equipped with two modems and two demodulators, providing two transmit chains and four receive chains.

PUT TO THE TEST

We have recently tested a new modem, conforming to EBU requirements, namely the SDM-9000 from EFDATA Corp. in the U.S. This modem has the advantage that it can handle up to four chosen data-rates between 6 Mbps and 52 Mbps. Modulation can be QPSK, 8PSK or 16 QAM, with various FEC ratios. The EBU requirement is 8 Mbps and 34 Mbps using QPSK modulation with 4/3 FEC.

QPSK (Quadrature Phase Shift Key) modulation varies the carrier phase in 90 degree steps. Clearly there are four phases available in 360 degrees, so each phase or sym-

bol represents a combination of two bits

(i.e.: 00, 01, 10, and 11). 8PSK uses eight phases, so it transmits three bits per symbol (i.e.: 000, 001, 010, 011, 100, 101, 110 and 111). 16 QAM transmits four bits per symbol using phase modulation and amplitude

modulation, with 16 possible combinations. QPSK is normally chosen for digital TV links because it represents the best compromise between required RF bandwidth and ruggedness. The relationship between symbol rate and composite data rate is as follows:

$$SR = \frac{CDR \times FECR}{B/S}$$

- where: SR = Symbol Rate
 CDR = Composite Data Rate, (i.e. basic data rate plus overhead data rate)
 FECR = Forward Error Correction Ratio
 B/S = Bits/Symbol for the chosen modulation system

The precise data rate of so-called 34 Mbps signals is 34.368 Mbps, to which must be added 96 kbps overhead data rate, giving a composite data rate of 34.464 Mbps. Hence for 34 Mbps transmission using QPSK modulation with 4/3 FEC:

$$SR = \frac{34.464 \text{ Mbps} \times 4/3}{2} = 23 \text{ M symbols/s, appx.}$$

The nominal RF bandwidth is equal to the symbol-rate, and the required channel-spac-

ing within a transponder to avoid crosstalk between adjacent channels is 1.3 x RF bandwidth. Hence the required minimum channel-spacing is 23 x 1.3 = 30 MHz approximately. Some modems under development are able

to adapt their operating rates to cope with varying conditions on the transmission path. For example, FLASH TV, a European transmission system for HDTV back-haul, utilizes 2 x 34 Mbps with 8PSK. It is designed to fall back to the more rugged QPSK if the satellite link suffers too much rain-fade. The HDTV signal then utilizes only 34 Mbps, providing a graceful bit-rate reduction rather than a catastrophic loss of signal.

Overhead framing is a feature of satellite

observe this quite easily by transmitting a PAL or NTSC vision signal to a geostationary satellite and displaying the return signal on a vectorscope that is phase-locked to the transmitted color burst. The return chrominance signal's vector display will revolve slowly due to the Doppler effect.

An SDM-9000 modem was installed at the Swiss PTT's Eurovision earthstation, which has a 7.6m dish. A 34 Mbps ETSI 300.174 digital TV signal was then sent from the Eurovision Control Centre via the modem to one of the EBU-leased transponders of Eutelsat II/F4. The return signal was received back at the Eurovision Control

EFDATA Corp.'s SDM-9000 satellite modem

Centre via the modem and decoded to PAL and 270 Mbps, so picture quality could be monitored. Its RF spectrum was also monitored using a 3.7m dish at EBU headquarters to feed a spectrum analyzer.

Figures 1 and 2 show the resulting spectrum, with nominal EIRP (70 dBW) in Figure 1 and 48 dBW in Figure 2, this being the lowest EIRP producing an unblemished picture back from the satellite. The 34 Mbps spectrum can be seen on the left of the two displays, with an 8 Mbps vision signal and a Euroradio 2 Mbps signal going from left to right in Figure 1, and one 2-Mbps signal plus an analog TV signal going from left to right in Figure 2.

The orthogonal transponder carried one analog TV signal during the tests, and this was offset in frequency with respect to the 34 Mbps signal so there was very little cross-polar interference. This explains the more-than-adequate link margin of 22 dB. This figure would be approximately halved with fully loaded transponders in both polarizations.

The SDM-9000 modem is a compact unit (the modulator and demodulator are combined in a 2U/19-inch unit) with user-friendly comprehensive diagnostic facilities. The availability of up to four data rates will be appreciated where data-rate flexibility is required. ■

Figure 1.

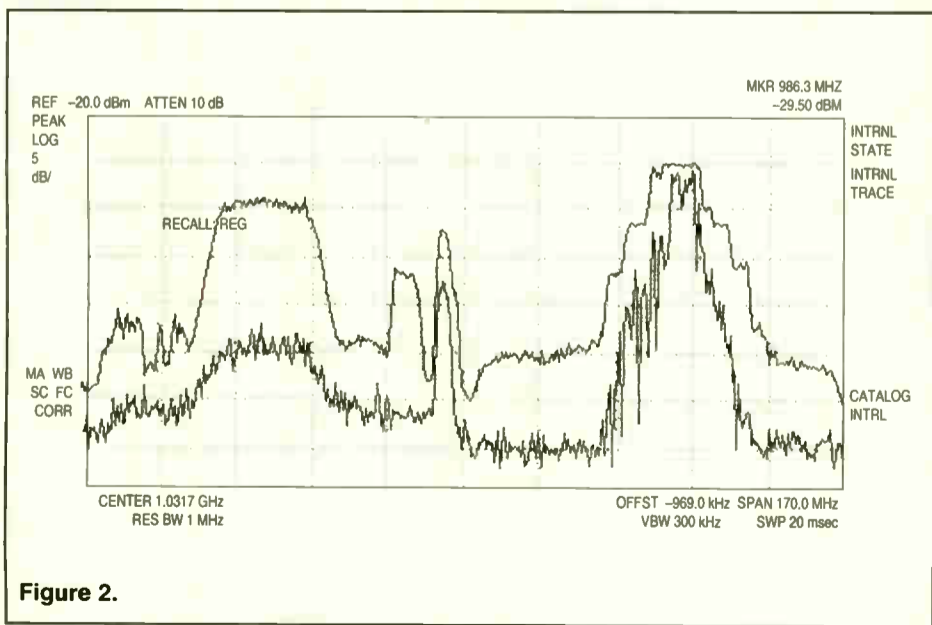

Figure 2.

Some modems under development are able

use between earthstations. With a duplex connection, this provides communication between the earthstations to monitor the performance of the link and take corrective action if necessary. For example, it provides a means to continuously monitor the BER (Bit Error Ratio) of the link. The SDM-9000 overhead framing provides two 32 kbps audio channels, one 8 kbps data channel and four backward alarms that can signal demodulator reception problems back to the modulator in the case of a duplex connection.

DATA IN MOTION

DATA IN MOTION

An essential feature of a digital TV satellite modem is the data buffer. It should have a capacity of about ±32 msec, which is necessary to ensure a correct bit rate from the demodulator despite small frequency changes due to the Doppler effect. This is caused by movement of the satellite relative to the earth. In the words of my colleague, Bill Potter, "geostationary satellites are not bolted to the sky!" They move over a 24-hour cycle relative to the earth, and the relative motion is fast enough to produce noticeable Doppler frequency shift. You can

Brian Flowers is head of service and project manager for the European Broadcasting Union's new Eurovision Control Center in Geneva. He studied engineering at the University of Southampton and served for two years in the Royal Air Force before joining the BBC. In 1962, he was assigned to the EBU's control center in Brussels and has since worked at numerous levels of responsibility for the center. He is a member of the Royal Television Society.

Light!

The fastest ignition in the world.
A new generation of electronics.

1 Sachtler's new solid state ignitors work quickly and quietly now in all Sachtler daylight systems.

2 Reporter 200 DI – introducing the latest reporter daylight from Sachtler: more light output from 200 watts than ever.

3 New electronic ballasts for Sachtler's reporter daylights: **Batronic 1** for 125 W and 200 W, **Batronic 2** for 125 W, 200 W and 270 W. The Batronics automatically sense which one of these fixtures is connected and will power it

accordingly. Four LEDs indicate how much running time remains. A switch allows selecting the proper dimmer range for HMI and MSR bulbs.

4 Sachtler Belt Pack, the well proven NiCad battery powers the whole range of Sachtler reporter daylights. Available in two sizes for 30 and 45 minutes of full light output from a Reporter 200 DI. Shaped to fit the human body and forming a compact unit with the Batronic.

5 The **Speedcharger**, controlled by its micro-processor, senses the state of the battery and charges it speedily and safely.

6 **Netronic 2:** The all new mains powered

electronic ballast for continuous operation of all Sachtler Reporter fixtures.

The most sophisticated reporter daylight system on the market today. By Sachtler.

Support & Lighting

Satellite Terms from A to Z

During a recent conversation with a fellow engineer, I mentioned that we had problems with our affiliates not having the proper LHCP feed, a LNB that was not PLL, and that many of their antennas did not have the correct FD at the feed. I knew I was in trouble when his eyes glazed over and he took on a rather blank stare.

So I repeated my statement filling in the acronyms with real words. "We have problems with our affiliates not having the proper Left Hand Circular Polarized feed, a Low Noise Block downconverter that was not Phase Locked Looped, and that many of their antennas didn't have the correct Focal Distance at the feed."

This made more sense to him, but it made

me realize that our industry has become very obsessed with acronyms. Although acronyms were once the mainstay of the military and telephone companies, they have now given our discussions in satellite communications a whole new sound.

To assist those new to the industry, and maybe even a few who have been around awhile, I have put together my top 86 satellite acronyms. I think you will find some "commonly" known; such as AM and FM. But I am sure you will find a few acronyms that you have heard but did not really know the correct meaning.

AGC — Automatic gain control, a circuit that provides for a fixed output, compensat-

ing for varying input levels.

AM — Amplitude modulation, also known as Ancient Modulation, not a modulation scheme used in satellite communications.

APS — Antenna Positioning System, a mechanical/electronic system used in pointing the antenna at the satellite.

BER — Bit error rate; digital circuits performance is often measured as a BER, or the probability of a digital bit being received correctly.

BO — Backoff of the power amplifier, given as a negative number, an amount of power reduced to avoid saturating the input to a satellite transponder.

BPSK — Binary phase-shift keying, a form of phase modulation in which two phases

by Phil Dubs

VIA SATELLITE

represent binary levels.

CDMA — Code division multiple access, a spread spectrum scheme transmitting on a bandwidth much larger than needed but at a much lower level.

CONUS — Continental United States (contiguous 48 states)

C/N — Carrier-to-noise ratio, a value expressed in dB; good satellite links have a C/N of 10 db or more.

CW — Continuous wave, a signal at specific frequency that does not vary.

dB — decibel, used in various satellite expressions, provides for an easy way to write and understand both very small and very large ratios.

dBi — Antenna gain in decibels, relative to an isotropic antenna.

DBS — Direct Broadcast Satellite, also known as DTH (Direct to Home) or TVRO.

DC — Direct current, the stuff you get from a battery.

DSBSC — Double sideband suppressed carrier, an outmoded modulation scheme (see AM).

EHF — Extremely high frequency, 30 to 300 GHz

EIRP — Effective isotropic radiated power, stated as dBi when referring to the effective gain of an antenna.

EOL — End of life, in regard to a satellite's useful lifetime.

f/D — Focal distance to diameter ratio, the ratio of feedhorn distance to the center of the antenna divided by the diameter of the antenna.

FDM — Frequency division multiplex, a simple approach to multiplexing in which each signal is assigned a specific frequency and bandwidth.

FDMA — Frequency division multiple access; simply put — putting more than one signal through a transponder at a time.

FEC — Forward error correction, used with a digital signal to send the correction information before the actual signal data is sent.

FM — Frequency modulation, a scheme in which the signal modulates the frequency of the carrier.

FSK — Frequency shift keying, in which binary levels are expressed with a shift in frequency.

FSS — Fixed satellite service, a satellite service in which the ground station is at a fixed location.

GEO — Geostationary or geosynchronous orbit, in which the satellite is stationary in respect to the earth.

GHz — Gigahertz (1,000 MHz)

GMT — Greenwich Mean Time (like in England)

G/T — The ratio of antenna gain (G) to the antenna system noise (T); a figure of merit, the higher the better; typical G/T specs are in the 20s and 30s dBi/K.

Hemi — Hemispheric beam, when describing the footprint of a satellite transponder.

HF — High frequency, 3 to 30 MHz

(continued on page 18)

TV BROADCASTING

16 FEATURES

SONY AND ANTON/BAUER ARE MAKING HISTORY..

Unpredictable shooting interruptions that occur with primitive "low battery" indicators are now history. Through a special InterActive™ circuit in Sony camcorders, such as the new BVW-D600 Betacam SP DSP camcorder, actual remaining battery capacity is transmitted to the viewfinder from the Anton/Bauer Digital battery's fuel computer. During operation, this highly accurate fuel gauge is displayed in the viewfinder and constantly updates remaining battery capacity to the cameraman.

Short runtimes, cumbersome battery belts and battery change disruptions are history. The Anton/Bauer InterActive battery and charger system deliver the high level of performance, reliability, and versatility demanded by the Sony Digital 1000 camcorders. A single high capacity Digital Propac® battery perfectly balances the camera on the shoulder and powers camera, recorder and Ultralight for 2 hours.

High wattage on-camera lights, wasted battery power and "interrogation room" interviews are history. The advanced low light sensitivity of the BVW-D600 is enhanced dramatically by the Studio Quality Ultralight 2. Automatique™, an exclusive control circuit standard on all new Sony camcorders equipped with an Anton/Bauer Gold Mount™, synchronizes the on/off function of the Anton/Bauer Ultralight™ with the VTR stop/start button. The Ultralight's photometric design matches ambient light to transform a shadow filled scene to a studio image.

These history making advances are possible only with the Anton/Bauer InterActive system, part of the innovative technology and creative solutions in the BVW-D600.

antonbauer The worldwide standard

The BVW-D600 Betacam SP DSP camcorder, and the DVW-700 the world's first Digital Betacam camcorder, feature InterActive™ viewfinder, Ultralight Automatique and Sony's exclusive Hyper-HAD™ sensor with OCL (On-Chip-Lens) technology.

Tracking the State of Our Art

by John Watkinson

VIDEO WATCH

In this article I have taken a possibly controversial look at a few contrasting subjects in order to see where the state of the art lies and where it is going.

What is possible today has gone beyond what many people grasp, and one has to avoid using words like obvious because the obvious is often missed. The art of making advanced products is to use technology to bring down the cost of the possible. But sometimes the possible turns out to be quite easy because the physical principles which allow it simply had been overlooked.

We have come a long way from the days when television meant PAL, SECAM or NTSC. As far as the viewing public is concerned, these systems do the job reasonably well, provided that standards or codes of practice are upheld so that the picture quality reaching the transmitter is reasonably close to what the format allows.

Casual observation in Europe, Russia and

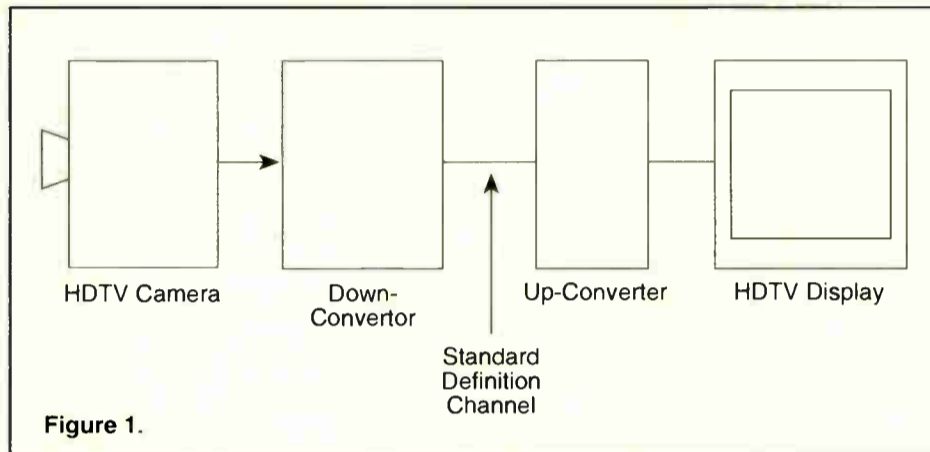

the United States reveals to me that the best adherents to quality standards in broadcast material are Europe and Russia, with standards in the United States a long way behind. Watching the technical quality of much U.S. television off-air reveals a regrettable excess of corner cutting and neglected maintenance.

This year's NAB could be an opportunity to check whether I am biased or close to the mark. Why not find out for yourself what NTSC is capable of by looking at some D-2 or D-3 demonstration material at the show, and comparing the quality subjectively with the TV set in your home or hotel room?

Having performed such a simple test myself at trade shows in Montreux, Amsterdam, Brighton, Moscow, Washington and Las

future HD system is implemented in the U.S. with the same lack of rigor as is used with NTSC today, I expect the results on screen would be no better than a rigorous implementation of NTSC. In which case, why bother with HD when it would be much cheaper to keep the existing format and make it work properly?

There is now quite a lot of HD hardware around, and the collection of material shot on HD is growing, along with the demand for down-convertors to allow the material to be delivered in existing formats. Viewing down-converted HD material on a good standard definition (SD) monitor gives results which are appreciably better than SD material on the same monitor. Why is this? Well, the combination of the HD camera and

Vegas. I can assure you that the last two come off worst. Small wonder that there is pressure to create a high definition (HD) system for the United States. However, if a

the down-converter is actually an oversampling camera. An SD camera cannot reach the resolution that the format theoretically allows because of aperture effect. In an HD camera, the aperture effect is still there, but it occurs at twice the resolution, so the camera aperture effect is absent from the down-converted material, which can reach closer to the theoretical resolution limit.

DISPLAY EFFECTS

Naturally, displays also have an aperture effect as well, and this can be overcome by up-converting an SD signal for display on an HD monitor. Again the result is better than viewing the same material on an SD monitor. Once more the display and up-converter together form an oversampling display, pushing the aperture effect of the display beyond the resolution in the SD signal.

The really spectacular result comes when these two processes are combined. As Figure 1 shows, an HD camera feeds a down-converter to produce an SDTV signal that is distributed along existing channels. At the receiving end, the SDTV signal is upconverted for display. Theory predicts that the perceived quality will be indistinguishable from HDTV, and practice bears this out. I know this to be true because I have seen it. If you have not seen it, you are missing out.

There are two morals here (God, I hate moralizing): First, the line standards or formats used for production and transmission need not be the same and can advantageously be different. Second, there is no need for a great increase in the number of lines transmitted, provided a greater number are used in production and display. Thus the problem of transmitting HDTV goes away.

In this digital age, it seems to be incredible to be discussing a new analog format, but that is exactly what PALPlus is. PALPlus has just started transmission in Europe and is a 16:9 aspect ratio transmission which is electrically compatible with traditional PAL receivers. This compatibility is achieved by transmitting 16:9 material in a 4:3 frame with black bars top and bottom, which is

exactly what you see on a normal PAL set, hence the alternative name of PALMinus: it is PAL, minus the top and bottom of the picture. If you have a PALPlus TV set, the few remaining active lines fill the screen height, and as you might expect, the vertical resolution could be impaired. PALPlus gets around this by sending a helper signal in the black bars which is invisibly encoded so that it does not show up on a 4:3 set.

TRANSMISSION EQUALS

As PALPlus is PAL-compatible, it uses the same transmission bandwidth and needs the same taboo channel structure to prevent interference. As a result, it delivers no improvement in transmission efficiency and occupies spectrum space which could carry several digital channels of equivalent quality. The real snag is that the helper signal system of PALPlus is patented and, if you are not a European manufacturer, getting a license is tricky. However, it is perfectly possible to build a 16:9 TV set which just displays the active lines. It is simply a normal PAL set with an interpolator and a different tube. The picture is softer, but you do not need a license.

My concern is that the public will not realize the difference and will end up with inferior pictures and blame it on the standard. We have a tradition of doing that in Europe, pioneered by BSB, which broadcasts technically excellent pictures in component form. Unfortunately, most viewers had decoders that convert the component signal back to composite so it could connect to the antenna socket of a conventional TV. We also have a tradition of devising TV standards in a way which can be loopholed. The patent-busting PAL TV set simply decoded every other line of the PAL signal as if it were NTSC. Technically inferior, but no license was needed.

The subject of compression has been uppermost in the minds of a lot of people for a couple of years now. Partly, the attraction must be the gee-whiz effect of new technology, but much of the attraction must be the perception that compression is some kind of answer to a prayer, a technology that gets a quart into a pint pot or delivers ten pound's worth for five.

Unfortunately, this is a simplistic view. The reality is much different. Now that some of the glamour of compression is fading, people are starting to realize that compression is a technology to be used wisely for specific purposes.

We can draw some parallels from existing analog video, which uses simple types of compression. Interlace is a form of compression. Bandwidth is halved in comparison to a progressive system. Interlace is a compromise because it allows resolution up to the number of lines in a frame, but not in the presence of motion. And it allows motion portrayal up to the field rate, but not in the presence of vertical resolution.

Interlace twitter and motion aliasing are interlace artifacts. Figure 2 shows that the finest video comes as GBR: three full bandwidth signals. This is too expensive for most purposes, so color-difference working is used instead. A luminance signal is produced with full bandwidth, but the color difference signals can have the bandwidth reduced to as little as one quarter.

This makes little difference to the viewer, because the resolution of the human eye to color detail is restricted in comparison with brightness resolution. Thus, the use of color difference signals is a form of perceptive coding, which is subjectively lossless. However, while excessive reduction in color difference bandwidth may be invisible to the eye, it also reduces the precision of chroma

USER REPORT

Hamlet Boosts Kuwaiti Upgrade

by Mahmoud Abdulnabi Al-Sayyid
 Director/News & Political Programs
 Ministry of Information

SALMIYAH, Kuwait

Our graphics department needed considerable reconstruction recently, including the installation of peripheral equipment for measuring the signal levels for transmission.

Our experience in projects of this nature indicated to us that level measurement equipment would be the last item on anyone's list of new products. However, our old studios contained old-fashioned CRT waveform and vectorscope products that provided measurement and monitoring under existing operating practices but were deficient in their clarity, over-engineered and not user-friendly enough for our needs.

For example, our graphics operators had some degree of experience using the CRT measuring devices. These were situated in a position as convenient as possible, providing the clearest possible view. However, the angle of view, brightness of display and ambient light levels always made operational assessment difficult.

AIR QUALITY

It is an important issue to maintain technical parameters while providing material for transmission. We required a more efficient

and flexible method of monitoring without compromising the importance of "within tolerance" transmission monitoring. So it was with great interest that we investigated the potential of the video scope method of television signal measurement and monitoring.

Clue Media, representing Hamlet products at that time, introduced us to the Hamlet on-screen, in-picture waveform and vectorscope units. It very quickly became apparent that our search for an alternative to the old CRT method had been achieved for us by an inventive company in England whose acclaim includes a current agreement to license Tektronix for its patented products.

Because our operators are not engineers, the equipment we wanted had to be easy to drive and to understand. By acquiring the Hamlet Video Scope, the veneer of mystique relating to the "CRT engineering units" had been swept away. The Video Scope puts test and monitoring within the grasp of all, for everyone to use and understand.

An important issue with the Hamlet Video Scope is that although it is a full broadcast device, it is not over-engineered. Rather, it is a very intuitive device. The main operational controls are all instantly available and clearly detailed without the need for menu-driven complications involving mul-

iple choice or multiple button-pressing to achieve a simple function change. In operational environments, this is essential to make life as easy as possible.

We chose the 301WV Hamlet Video Scope because it was quite clear it was capable of a lot more than we actually required, and therefore was a very good investment. The quality is excellent and the cost is very low in comparison to the bulky, expensive alternatives.

The higher-priced 304WV Video Scope was a possible choice for us. It is a full-functioned YUV/composite unit with more technical facilities, such as line select and SCH absolute readouts, bow-tie measuring, five-function set-up memory, simultaneously combined YUV and composite operation with multicolored trace and graticule displays. But all these modes were not required in the areas we were concerned with. The 303WV, although technically superior to the 301, was not chosen because it is only a composite unit.

ANALOG REQUIREMENTS

Our choice, the 301WV, is a one-rack-unit device, like the 303 and 304. It can handle nearly all requirements in the analog domain from just the one device. These include PAL, NTSC composite, component YUV, RGB and YC, providing waveforms and vectors in all these standards, plus the new HFT (hands-free timing) facility.

The 301 is also available with an audio option for linear PPM VU color bar graphics and polar display of the stereo image. We did not choose the audio option add-on card, but it does provide the component vectors, and we have been told that the unit is easily retrofittable.

Powered from either mains or 12VDC, the Hamlet Video Scope 301WV can be conveniently rack-mounted and remote controlled. If placed right in front of the user, it is no problem to transmit the combined trace and display signal to any monitor or LCD for more convenient study. The output can also be recorded for later examination.

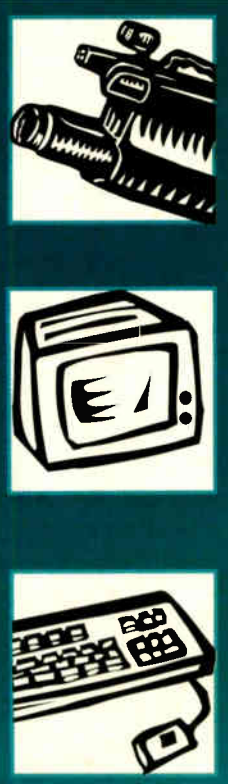

The small-screen displays, which can be placed at either top or bottom of the display plus the mix facility, further enable flexible monitoring. This mode is regularly used in our studio. The large screens are, of course, essential for real absolute analysis.

The unit's probe input can be of real value in which first line maintenance is required. The high impedance probe input found on the front of the Video Scope allows the unit to be used like an oscilloscope. The probe trace display is inserted into the reference input, which supplies the stable synchronization signal. The probe trace can then be easily investigated. When used in this mode, the unit may be re-calibrated to show either smaller or greater signal levels.

We have recently discovered that the probe input may be converted to act as another composite input. In this mode, the unit has the capacity to provide four composite inputs or one component and one composite set of inputs.

Recently back from the Middle East Broadcast Show, I saw the new half-rack products, which include Hamlet's 302WVR

Philips Turns to ShibaSoku

by Victor G. DeGutis
Manager
Philips CE

EL PASO, Texas

The passage of the NAFTA (North American Free Trade Agreement) in January 1994 led Philips Consumer Electronics Corp. in the U.S. to re-evaluate its warehousing and distribution procedures. The company decided to locate central warehousing in El Paso, Texas, importing products from Pacific Rim countries and televisions assembled in Mexico.

Warehousing in El Paso resulted in the establishment of a product assessment lab on site. This lab has added to the efficiency of the distribution system by limiting the amount of time (in transportation) and money (in delayed sale of product) required to send product samples to the main evaluation center 1,700 miles away.

To facilitate product quality evaluation, a central signal system was established to make color television product assessment possible. This system facilitates the distribution of local TV signals to five test stations, allowing the generation of test patterns to meet specific needs.

THE EARLY DAYS

In the early days of television, an "Indian Head" monoscope test pattern was used as the evaluation basis. Now, we use the ShibaSoku Company's Model TG21A1 test signal generator, with a monoscope pattern board, which does the work previously accomplished by the monoscope but with additional features.

The monoscope pattern consists of a peripheral 50 percent gray pattern, which allows the evaluator to observe the gray scale tracking. In other words, if the white appears "white" at a given color temperature, the gray should appear gray at a lower luminance level.

ShibaSoku's operating instruction manual provides sufficient technical information to facilitate the training of semi-skilled employees in evaluating color television video performance.

Among the TG21A1's features is a number 30 in the center of the display, which allows technicians to check the focus of its central area, plus the number 30 appears in the corners for "corner focus" evaluation. The unit can test for convergence, symmetry and resolution presentation.

Test patterns are used to determine horizontal and vertical overscan, and out-of-specification deviations are reported back to the production facilities. By turning the color burst on or off, luminance channel performance can be determined.

In addition, this ShibaSoku model carries a dozen additional switchable video test signals that operate independently and sepa-

rately from the monoscope presentation. These standard signals include the SMPTE color pattern, multiburst of six frequencies, the 2T pulse and bar, matrix and the familiar crosshatch or convergence pattern.

The TG21A1, with the TG21A1002 monoscope pattern, is used to feed two TV modulators, and the selectable video

output provides the signal input for a third modulator.

SIGNAL SELECTION

In the future, the GP-IB port may be used to vary the selectable signals automatically. However, manual selection of the video signal is sufficient for our purposes.

When the unit was ordered, we considered the possibility of check-

ing PAL color receivers for marketing in Latin America. We decided that purchasing the PAL features with the EBU pattern intact was more economical than having this feature added in the future.

The local 32-channel cable system provides real-time color television signals, which we use for a generalized customer-oriented evaluation of receivers. The TG21A1 unit adds a monoscope signal and a choice of 12 other signal sources all in one package, making more in-depth performance evaluations possible. These evaluations can be accomplished

by semi-skilled workers who have been provided with specific training regarding the characteristics of the test signal generator. ■

Editor's note: Vic DeGutis is the manager of Philips Consumer Electronics Corp.'s Product Assessment group in El Paso, Texas. He has worked in color TV design, development and production.

INTRODUCING THE PAG MC124

The ULTIMATE in charging technology

**INCORPORATING
PAGACS™**

Whenever or wherever you are on location the new PAG MC124 represents the very latest in battery control technology. The charger is designed to provide workshop facilities for the management of any mix of Ni-Cd batteries in the range 4.8V to 14.4V, 1Ah to 7Ah.

The PAG MC124 features include an LCD display which indicates the number of cells operating and the charging current loaded for any battery under process; an 'Autoranging' charge facility; a serial port for connection to a PC and a 'Widerange' input supply, for use world wide. The PAG MC124 can also be powered from a 12V DC supply via the PAG Vehicle Battery-Power Converter.

Although PAG MC124 is a stand alone unit it can be controlled from a PC via PAG CMS (Charger Management Software). PAG CMS operates in an

easy to use 'Windows' environment. Test results and superb high resolution graphs are available on-screen in real time, and as hard copy.

PAG MC124's battery control system is upgradeable to accommodate future developments in battery technology.

PAG have taken battery management into a new dimension, once again demonstrating the ability to design for the needs of tomorrows cameramen - today.

USER REPORT

Vistek Keeps Meridian on Top

by Roger Pearce
News Operations Manager
Meridian Broadcasting

KENT, U.K.

Meridian Broadcasting is part of the ITV network in Britain. Our franchise covers the south and southeast of England, including most of the area from the suburbs of London to the south coast.

Our strength is in our regional programming, in particular, our award-winning news service that feeds the region via regional news centers.

In 1994, we built a state-of-the-art news center in Maidstone, Kent, for our south-east region. Across the board, our budget called for cost-effective solutions without compromising technical performance.

The critical vision paths are in the component analog domain. PAL monitoring

would be needed for secondary inputs and for transmitter checks. When it came to choosing our monitors, we were basically looking for no-frills, stable and high quality units that would deliver reliable monitoring at a reasonable price.

LONG HISTORY

Vistek has a good track record in the manufacture of broadcast equipment and was well known to us as a reliable supplier. With a view to minimizing familiarization and maintenance time, we were keen to get as many monitors from the same manufacturer as possible.

After considering other suppliers, we decided that the Vistek range offered the quality, choice and prices we were looking for. Our general Grade 2 color monitoring is provided by the GM 7237 14-inch unit. This had only just come onto the market at the time of our order and seemed ideal for general purpose monitoring in edit suites and control rooms.

The 7237 offers very similar features to the Grade 1 GM 7537 but with a lower grade tube (and price). Technical performance has been impressive with a perfect reliability record.

As we move toward a future with more all-color monitor stacks, it is crucial that color balance is stable. Vistek has created a Dark Current Stabilization (DCS) system to compensate for drift in the gun emission currents during warm-up and with aging tubes. Two other important factors for us were geometry and size stability: both have been good.

Rotary encoders are used throughout the Vistek range for front panel adjustments, such as brightness and saturation. Other

settings, such as black level, gain, preset contrast and brightness, are stored as binary values in battery-backed RAM. These values are recalled at power-up and fed to multiple DACs to provide analog control voltages.

For line-up, we looked at the analyzer probe option but decided that our mainly monochrome stacks did not warrant the extra expense. Stability would be essential, but our experience has been good so far.

Another factor in our decision to buy the

vided both to a high technical standard. Grade 1 monitoring positions in graphics and engineering use GM 7537 14-inch and GM 7551 20-inch monitors.

In addition to the digitally adjustable presets, Vistek provides conventional rotary potentiometers for primary controls, such as brightness, saturation and hue/phase. We have found this to be a useful provision for engineering checks and equipment maintenance. Both provide accurate and stable viewing with a wide selection of features available from the front panel.

The Vistek range of monitors has neatly fitted our requirements, offering keen pricing and comprehensive specifications backed up by an excellent reliability record. Meridian is a leader in providing efficient,

Vistek has created a Dark Current Stabilization (DCS) system to compensate for drift in the gun emission currents during warm-up and with aging tubes.

GM 7237 was that input format was very flexible. Plug-in input modules are used to provide the required system configuration. We will therefore be able to change to digital formats in the future at minimum cost.

COST BALANCING

In our production control room, we chose GM 8223 monochrome monitors for secondary monitoring. These provide basic features at a reasonable price. Tube phosphors are consistent and closely match the primary color monitors. It is always difficult to balance cost against the grade of a tube, but these Grade 2 monitors have turned out to be a good choice.

The primary color monitors in the production stack are 20-inch GM 7251s. We were particularly looking for accuracy and consistency, and so far our monitors have pro-

high quality news resources, and as a consequence we demand the finest standards of reliability and stability from our suppliers. This enables maintenance back-up to be kept to a minimum.

Vistek has always been keen to fulfill our needs and to develop a good relationship with us as a customer. ■

Editor's note: Roger Pearce has worked in the broadcast industry for more than 20 years. In addition to Meridian, Roger has been employed at such U.K. broadcasters as TVS Television and Grampian.

The opinions expressed above are the author's alone. For further information on Vistek's line of monitors, contact the company in the U.K. (Telephone: +44-628-531-221; FAX: +44-628-530-980), or circle Reader Service 60.

CONTINUED FROM PAGE 30

Hamlet Puts Kuwait TV On The Level

Video Scope and 503AR Stereo Scope. The 503AR is strictly an audio device with four channels of PPM/VU color bar graphics and polar displays. So it is not required for a graphics studio.

The 302WVR certainly caught my eye, providing four composite or one component operation with the flexibility of adding another composite. Some of the nice new features include store and recall of up to eight function set-up memories, which makes parameter studies quick and easy. There is also instant return to black level, center position on the waveform and vectorscope, HFT hands-free timing, chop mode on all inputs and full screen, half and quarter size display combinations.

With its small size, this unit would be very useful either in a studio, sitting on top of a monitor or in the field. It also includes two audio inputs with displays of PPM or VU bar graphics on the vectorscope display.

The Middle East market is very difficult to get into, but it is clear that the inventive nature of the Hamlet Video Scope products have caught the imagination of many, and I understand that among other current users, Bahrain Television has three units that are used in editing suites recently installed by BTS. ■

Editor's note: Mahmoud Abdulnabi Al-Sayyid is responsible for news and political programming for the Kuwaiti Ministry of Information.

The opinions expressed above are the author's alone. For further information on the Video Scope line of products, contact Hamlet in the U.K. (Telephone: +44-494-775-850; FAX: +44-494-791-283), or circle Reader Service 37.

Film Maker Relies on Multidyne

by Robin Miller
Engineering Consultant
Film Maker Inc.

PHILADELPHIA, Pennsylvania

My first experience with Multidyne signal generators was while engineering a U.S. President's speech to a joint session of Congress. It was the NBC network's turn to feed the pool, and any member could access our sources via a remote control 10 x 10 switcher.

With seven cameras inside the Capitol and a 45-foot truck outside, our dilemma was assuring the world in advance that they would get a good signal. Beyond televising zero defects, we had to also assure that this signal would be the feed they wanted.

PEACE OF MIND

Any remote producer can tell you that there is little peace of mind at the remote site until "Goodnight" is sent. Receiving stations, networks, carriers and international clients can be the powerless victims of an unlabeled feed.

Every remote should assure stations receiving feeds that they will broadcast the intended program without airing "Due to technical difficulties..." This only results in lost viewers.

For this President's historic speech, we used multiple Multidyne generators so that every feed had its own bars, tone and descriptive ID. Why? In the end, to save trouble.

The typical alternative would have tied up our producers' telephone lines with dozens of client stations reporting various problems.

On a simple remote, a typical truck's bar generator has ID capability. However, the demand for international and other multiple feeds has spawned battery-operated "Swiss-army knife" test generators with programmable messages and tones. It is

not enough to have 12 characters of ID.

I have come to rely on Multidyne's TS12 in both portable and rack-mounted form. It offers high signal quality assurance in either 8 bit or 10 bit versions. In addition, the TS12 features 32 character ID and audio channel identification and synchronization verification with picture, which today can arrive by a delayed path through one or more frame syncs.

If remote broadcasts remained simple, the truck's one SSG with ID would suffice. However, multiple "split" feeds to several clients who share remote facilities have become more and more the norm. For these, multiple test and ID sources are

either eight or 10 bits of video precision, plus several options. All have separate continuous black burst output, which can serve as a master genlock reference.

For digital recording and transmission, both compressed and uncompressed, Multidyne offers the new 95-100 ramp, which allows accurate signal-to-noise and

the benefits of avoiding transmission troubles will value it also.

For proof of the unit's performance, we ran it through a Hewlett-Packard 54602B scope using BenchLink software. The TS12 offers excellent signal standards that exceed anything you are likely to calibrate with them.

The readouts we got for magnified horizontal interval are textbook RS-170A. Also, multipulse signals have a flat response and no group delay is present at sc frequency.

The NTC7 composite showed an undis-

**Today's TS12 is physically tough,
electrically stable and ergonomically usable . . .**

The TS12 is available in either 8-bit or 10-bit versions, portable or rack-mountable.

needed with one for each feed. Carriers as well as television trucks need to provide sources, seeing as it is cheap insurance.

MULTIDYNE'S SOLUTION

The Multidyne TS12 is the solution to remote peace of mind. The TS12 has 12 standard video test signals and 16 programmable messages (battery-backed) for remotes, production and general maintenance. It is available in four flavors: battery-handheld and rackmount in

quantizing signal-to-noise measurements with a VM-700A. For on-air, sinX/X allows spectral analysis. Also, up to a 14-second audio ID can prevent airing the right picture with the wrong sound.

Today's TS12 is physically tough, electrically stable and ergonomically usable without having to study a manual. While the rack-mount version's panel looks uncomplicated, it is not only beautiful to engineers, but accountants as well. Producers and managers who appreciate

torted 2T that was exactly twice T (125 nsec). The unit also provides excellent reproduction of multiburst.

Also available is a useful 5 MHz sweep with markers at 1, 2, 3 and 4 MHz. We also have the NCT7 combination and composite lines as VITS on every selection except black burst. They are also added along with readable ID in the vertical interval of video that was passed through the rack-mount version.

With the 10-bit TS12's quantizing signal-to-noise of -84dB, the new ramp function allows accurate digital recording or transmission performance using a slightly varying reference rather than an artificially quiet, single table lookup at ØIRE (usually of line 12). The sin X function provides an accompanying Fast Fourier spectrum that is flat and homogenous in the "infinite" frequency components that sinX/X generates.

FUTURE REMOTE SCENARIO

More channels, more program providers and more carriers can mean more possibilities for the wrong patch cord or router crosspoint selection at the wrong time.

Consider the telecom room at a busy venue. Often it is a mess of wires in a steel cabinet near where the truck will park (next to the dumpster). Long before the expensive truck arrives to send bars and tone, the carrier sets up one or more paths to the world with a test/ID generator feeding each.

Teleconferences, Distance Learning, and other "occasional networks" can leave a lone Multidyne TS12 at the origination or "demarc" point to feed both visual and audible (spoken by the TS12) because it switches automatically to test/ID if no video is input to it after six seconds. Everyone along the transmission path can confirm this in an instant on his or her own. During the event, ID can appear in the vertical interval for instant confirmation.

In addition to their TS line, Multidyne will introduce fiber-optic devices, GV compatible DAs, and small routers at NAB. However, if they just made good test/ID generators for your money, peace of mind would not be so remote. ■

Editor's note: Robin Miller is a broadcast marketing engineering consultant and an award-winning producer and director.

The opinions expressed above are the author's alone. For further information, contact Multidyne in the U.S. (Telephone: +1-516-671-7278; FAX: +1-516-628-1496), or circle Reader Service 99.

ELIMINATE PODIUM CLUTTER.

PB2X8 Pressbox/Microphone Distribution System MICROAMP SERIES

Eliminate the usual press conference microphone clutter with just a single or a back-up pair of microphones.

Feed each of eight transformer isolated channels from either input or both Mic/Line inputs mixed.

Drive a high level XLR and a medium or low level TRS line simultaneously from each output.

Use as a 2X8 DA, stereo 1X4 DA or two input mixer.

Studio grade performance, field proven ruggedness.

- Rack or desk mount
- Two low noise Mic/Line inputs
- Phantom power, low cut filter
- Loop thru expansion inputs
- Calibrated test oscillator
- Switchable bargraph VU meter
- XLR, 1/4" and 3.5mm TRS jacks

Character Building

Aston have built a reputation on quality, versatility and reliability.

Add to that our latest innovative designs, and you're looking at the most exciting range of character generators available today!

Already the industry workhorse, Motif redefines today's broadcast standard for affordable typography, whilst Motif ESP adds an extra static plane to give your presentations a versatile new dimension. And now there's the new Ethos - Aston's most powerful character generator ever - featuring full dual channel, amazing speed, and text animation that will blow your mind! With the File Server to manage your captions and graphics, it's time you took another look at Aston.

Magni Takes Impact to the Limit

by Doug Hembruff
President
Impact Televideo Productions

ONTARIO, Canada

I recently had an opportunity to use the WVM-710 Automated Video Signal Monitor from Magni Systems in our editing suite at Impact Televideo Productions. This full-featured waveform/vectorscope/auto-measurement device is one rack-unit high, displays on a standard monitor screen and simplifies signal measurement so that users can concentrate on creative content.

Magni has incorporated so many features into this little scope that I find it difficult to do justice within the length limitations of this article. True to form, Magni has managed to keep the WVM-710 at a list price substantially less than most other scopes with similar features.

The Magni WVM-710 should appeal to a wide range of users, but the largest market seems to be editing suite operators who want to spend their time creatively, not with one eye always on the scope.

ON-SCREEN WARNINGS

To this end, the WVM-710 has several user-definable limit ranges. It offers on-screen pop-up warnings over the video picture, or a full-screen waveform that instantly shows red on any part of the signal that goes out of limit. The only thing it does not

do is reach out and slap you if you are not paying attention.

Remote scoping is another popular application. With a modem pair over telephone lines or RS-232 cable and "Logbook" Event Manager software, TV stations can spot-check an antenna site. Editing suites with VTRs in another room can check the output without worries of signal loss over long cable runs.

In addition, the high resolution 10-bit rasterized video scope display has built-in graticules for accuracy. The waveform and/or vectorscope display can be full or 1/4 screen.

Plus, all displays have a choice of black opaque background or semi-transparent over the video picture. When there is a problem, several out-of-specification "icons" (picture guard) can automatically pop up over video.

On full-screen, you can superimpose the vectorscope over the waveform in a different user-definable color, as well as add a stereo audio meter. In addition, the video screen outputs for the scope are composite or Y/C, and are separate from the loop-through outputs. When using any of the auto detect features, quality control of transfers from videotape to non-linear systems can be more easily maintained by non-technical persons.

There is a "Venetian Blind" split-screen-type display that alternates the picture between channel "A" and external reference at 32-line

intervals. These two signals will horizontally offset each other if video signal timing does not match the reference signal. This allows quick and easy matching of timing, luma, chroma and hue to the reference signal without having to know how to read a scope.

There are also two sets of screens that mea-

and other parameters are also captured.

Also, the Magni WVM-710 can store six scope readings for later recall. These can be sent directly to a printer without a computer because several standard printer drivers are built in. The logging or hard copies could be a real labor saver for broadcast stations that are required to keep regular records of video signal integrity.

It can also be a great diagnostic tool for an engineer to track down intermittent problems or compare to previous readings. Other applications for this automatic logging are

The Magni WVM-710 stores six vectorscope readings for later recall.

sure 16 video parameters using numeric displays and a two-colored bar graph showing whether they are in or out of acceptable range. A menu allows the user to adjust a minimum and maximum range of acceptability. These 16 measurements are luma amplitude, chroma amplitude, chroma phase, setup, sync level, burst amplitude, peak video, horizontal reference timing, SC/H phase, color frame, luma noise level, chroma/luma/gain, chroma/luma delay, differential phase, differential gain and pulse/bar.

For these parameters, as well as the waveform and vectorscope, it is possible to select the line to measure and whether it should be an even or odd field pair. There is also a VITC time code display with hours, minutes and seconds, but not frames.

The VITC can be selected from lines nine through 25. There are graticule marks that indicate proper horizontal blanking settings such as sync width/position, burst width/position and horizontal limits of the active picture.

CHOICE OF INPUTS

The Magni WVM-710 works with NTSC or PAL, and users can select two different inputs in loop-through mode (there are one component or RGB 15.75 kHz, two composite and one Y/C 3.58). Computer graphic artists or character generator operators would find the WVM-710 a handy tool to keep within legal limits because of the automatic warnings. Computer-generated video has a much greater chance of exceeding legal chroma video limits because 25 percent of the RGB pallet choices are not legal.

The optional "Logbook" software allows unattended signal monitoring and logging at specified polling intervals as often as one minute apart. Time stamp and storage of the waveform, vector, auto-measurement screens

overnight transmissions and quality checks on tape duplication using vertical interval test signals (VITS).

Among the many valuable menu settings is one that changes the internal reference from Crystal Lock to VCR Lock for better jitter-free images when scoping an unstable source, such as a VCR without time base correction.

The Magni WVM-710 also has some nice features that I did not expect to find. There is a VITC time code readout, a stereo audio display that indicates levels and phasing, a luma signal-to-noise measurement usually only found on extremely expensive scopes and a safe action (5 percent off each border), safe title (10 percent off each border) outline generator.

This versatile Magni WVM-710 automated video signal monitoring system is a "must have" scope for many production houses, TV stations and engineers. Magni maintains a toll-free customer support line along with a free BBS for software and bulletin updates. I also found Magni's instructional documentation to be much better than average. ■

Editor's note: Doug Hembruff is a corporate and broadcast video producer at Impact Televideo in London, Ontario. He performs beta testing and product evaluations, in addition to his technical writing. Doug is currently doing field production in Israel.

The opinions expressed above are the author's alone. For further information, contact Magni in the U.S. (Telephone: +1-503-626-8400 ext. 634; FAX: +1-503-626-6225), or circle Reader Service 39.

Facing the Future

Imagine a specialist in electronics, the type always surrounded by instruments and electrical circuits. Invite him to visit the C.R.S., a company that produces television transmitters...

...I was immediately struck by the incessant noise of the machinery. I started to think how strange it was: "Today electronics doesn't make any noise". Inside: lathes, milling machines and five NC machines. These robots mould bronze as if it were clay. Complicated mechanical pieces rapidly take shape under the implacable graver of the "electric" artist. I get it! The C.R.S. is a company of mechanics! Mistake! Only a few steps and I discover a highly complicated board for measurements. Video generators, network and spectrum analysers and everything anyone hooked on measurements would dream of. I'm confused now, mechanics or electronics? An elderly engineer smiles and calmly explains to me how the C.R.S. has managed to happily combine mechanical precision with electronics. For example they produce a solid state amplifier costing the same as a tube amplifier but simpler and more reliable. Its international patent places the C.R.S. at the forefront of this field. Although some time has passed it is always a pleasure to return to this "unusual" company where we talk about the past and the future. Times which do not coincide with those of other producers. The future of most companies is now in fact on the workbenches of the C.R.S., whereas the distant future "of the others" is already in the desk drawers of their designers.

USER REPORT

Tek Preserves Quality VTRs

by Attila Bitto
Sony Electronics Inc.

TEANECK, New Jersey

As service professionals for the Sony Customer Service and Engineering Center, we want the machines we refurbish to fully meet our specifications when they leave the facility.

For Sony's studio-quality Betacam SP VTRs, this means testing several dozen video and audio parameters. In fact, because these tape decks provide both metal and oxide operation, each parameter must be tested twice — once for each primary operating mode.

AUTOMATED TESTS

Here at the center, we have automated the parameter test process. Using a Tektronix VM700A Video Measurement Set, driven by a Windows-based software package developed here, we have reduced the time needed for full video and audio parameter verification from hours to minutes. Best of all, because the process is fully automated, we can count on consistent, reliable results every time.

Located just outside New York City, the

Teaneck facility is a high-volume regional service center that supports many of the nation's leading broadcast and production studios. We are the second largest of Sony's five U.S. service centers, with 12,000 units coming through each year to be tested, repaired or rebuilt.

The VM700A was the logical choice to help us increase the consistency of our VTR testing. Built to monitor and measure video signals in real time, it is a full-featured system combining the functions of a digital waveform monitor, digital vectorscope, noise measurement set and data logger. Both numeric and graphic displays are available for a host of standard measurements such as DGDP, luminance to chrominance delay, K-Factor and so on.

Options extend the instrument's versatility and enable it to measure audio, component analog, teletext and even cameras. At Sony, we use the NTSC, component and audio options. In addition to final testing, we use the VM700A for spot diagnostics on incoming tape decks.

The VM700A is designed to interface readily to an external controller, and we have taken full advantage of this capability. Our software runs under Windows on an

Intel i486-based Compaq computer that connects to the VM700A, the device under test, a Tektronix ASG100 Audio Signal Generator, a routing switcher, a signal generator and a printer. Under software control,

number of samples taken, which allows us to optimize the speed and accuracy of the averaged results.

Building on this flexibility, we have developed multiplexed video signals that contain color bars, multiburst, linearity and other parameters in one signal. We can record a minute or two of that signal and configure the VM700A to make the proper measurements on the appropriate signals where they appear on the line.

The Tektronix VM700A combines waveform and vectorscope functions with a noise measurement set and data logger.

the VTR rolls to a specific segment of tape where the VM700A makes its measurement(s) and logs the results and prints a report.

UTILIZING PROGRAMMABILITY

We also make extensive use of the VM700A's programmability to minimize test cycle time and increase our assurance of quality. For example, the VM700A's Function mode allows us to measure non-FCC signals — a feature that lets us check the custom signals used on our factory alignment tapes.

By allowing us to specify where a parameter is measured along a line of video, we are able to perform "standard" tests on virtually any signal containing the correct elements. Another example of the VM700A's programmability is the ability to specify the

Then we multiplex the signal so that the pattern repeats several times, and use the VM700A's Block mode, which averages the samples throughout a field of video. Measuring this way provides an additional check on the RF signal envelope.

Our automated test system has been so successful that we are expanding its use. Beginning this year, all five U.S. service centers will use VM700A measurement sets with our Windows-based control application. ■

Editor's note: Attila Bitto has been involved with Sony customer service for 18 years.

The opinions expressed above are the author's alone. For further information, contact Tektronix in the U.S. (Telephone: +1-503-627-4697; FAX: +1-503-627-5801), or circle Reader Service 95.

BUYERS BRIEFS

Leader Instruments Corporation announces the release of Model 953, an advanced FM, VHF, UHF, CATV level meter called the CATV Spectrum Meter. Model 953 features both analog bargraph and spectrum displays with digital readouts on an LCD screen with frequency coverage from five to 1030 MHz. It contains all U.S. broadcast and cable channel formats, and can also be programmed for customized channel schemes for each local cable operator.

In addition, auto search and auto ranging sets up optimum measuring conditions for any situation. Up to 50 setup programs may be easily tailored and stored to meet the needs of individual systems.

Link introduces a new product to its 700 series. The Link IEC-787 is a one-input video inserter, which recovers signals in the vertical blanking interval. This includes Closed Caption data (Line 21), the Ghost Cancellation Reference signal (Line 19), and others.

Using front panel switches, any of the Lines 10 through 21 may be selected for insertion by the IEC-787. Odd and even fields are handled separately. Also, the keyer employs the same phase-linear circuit used by the LINK Closed Caption equipment to provide clean insertion. In addition, differential input configuration is standard on both video inputs, but single-ended configuration can be selected by an internal jumper. A switchable Monitor output allows the user to view either of the video inputs ahead of the keyer.

For more information, circle **Reader Service 58**.

Leitch Incorporated has introduced a simple and inexpensive solution to add EDH into multiple transmission paths. The technique is to incorporate on board EDH circuitry in a serial distribution amplifier.

The EDH-6800 distribution amplifier may be used anywhere where a standard serial DA can be used. It has the same equalization and reclocking features, plus the ability to insert an EDH signal into all eight outputs.

Use of the EDH-6800 DA's in critical path lengths throughout the digital television studio complex can alert any bit error problems developing within the system.

For more information circle **Reader Service 49**.

The Video Window by **ComSonics Inc.** is a digital video multimeter designed to meet today's NTSC and PAL formats. This hand-held meter can carry out 40 separate test functions, including the three major ones used worldwide — Differential Gain, Differential Phase, and Chrominance/Luminance Delay.

All test results can be viewed on Video Window's alpha-numeric backlit screen. Also available is an optional printer/PC interface which can provide additional in-depth study and analysis at the office, lab, or headend.

Some of the more commonly utilized measurements possible with Video Window are: Sync Analysis, Y R B Components, Color Match, Vectorscope (Phase and Gain-Chroma/Luma, Noise Measurement), Run Status, Waveform Monitoring, and Camera Shading.

For more information circle **Reader Service 81**.

USER REPORT

Philips Is the Star at Pisces

by Robert B. Peirce
Vice President
Pisces Productions

BOSTON, Massachusetts

Pisces Productions is an all-digital, full service post production house in the city of Boston. Since its construction in 1994, Pisces has taken full advantage of all component digital technology.

In the Pisces facility, computer, video and audio equipment have been integrated so that pictures and sounds can be networked between edit suites and computer rooms at will. Graphics accomplished on SGI Indigos, Macs and PCs can be shared, and video can immediately be passed to computers for printing or other purposes. In fact, some clients actually leave with their edits on computer disks rather than videotape.

DIGITALLY SOPHISTICATED

Despite this level of digital sophistication, analog video still plays an important role, while quality control demands accurate monitoring. For this purpose, we chose the Philips TV Test Model PM5662 waveform/vectorscope for our more critical applications. It was chosen mainly because it has two major monitoring functions in one instrument, and it is "operator friendly" for simple switching between waveform and vectorscope operation. It also includes direct SCH monitoring.

The most active use of one of the Model PM5662s is at the graphics camera position. A steady flow of paper, film, slides and other elements is placed beneath its lens, and CCU manipulation is constantly needed to get optimum pictures.

The monitor is used with external sync (house black burst) so that genlock and timing can be checked. The "A" side of the scope is fed by the camera control unit NTSC out, while the "B" side is patchable and any source can be routed to it. This is often used to feed back a composed and keyed picture to help the operator place art

under the lens.

At the upper right of the waveform monitor control panel is the rotary switch, which allows easy switching between the two signals. Meanwhile, the video output feeds the picture monitor. At the top of the panel, two LED-illuminated buttons give the choice of waveform or vector operation. Beneath these buttons are selections for various filters that can be applied. There is no magic — the filters are the same as those found on most systems, but their employment is simple.

When monitoring a waveform in the flat position, the entire waveform with chroma is displayed. However, when the LUM button is pressed, the waveform is split into a right half with full bandwidth and a left half with luminance only. Luminance levels can be set easily while still keeping an eye on maximum chroma. A separate filter is on its own selector button to display chroma only. This is helpful when diagnosing differential gain errors.

When using the vectorscope mode, the selectors allow either standard vectors or a special differential phase mode. A useful feature is the settings for the waveform and vector modes, which are held separately and make shifting back and forth between them easy. Plus, setups are kept as you want them.

The horizontal time base is always calibrated, so when blanking measurements must be made (a frequent occurrence here), the "X-MAG" button gives an immediate display, and tic marks along the baseline are accurate to one microsecond.

SCH PHASE CAPABILITIES

The SCH Phase is indicated by a dot on the outer circle when using the vector mode. When the burst is aligned on the horizontal line left of the center, the SCH dot should appear on the same line to the extreme left. A calibrated scale indicates the error in degrees from standard.

In an all-component digital plant, SCH would not seem to be important. In fact, some of the digital equipment is remarkably sensitive to SCH phase, so it is always a good idea to keep it correct. This scope makes it simple to set and provides a constant visual reminder of the current condition. For those not needing SCH information, a version of the monitor is available without this capability.

When the time base knob is rotated toward the left, a one-line display is selected from one or the other field, or both fields together. The actual line selected is chosen digitally with three numeric switches, which specify a line from 001 to, in our case, 525. This makes it easy to look at a particular horizontal portion of a picture, thus avoiding trying to spin a knob to find the location. For instance, it is an easy way to see if video actually starts on line 20 or 21, just by dialing the number.

The display is bright and sharp, in part aided by a front panel focus knob. There is sufficient brightness whether using a full display or a one-line setup. Scale illumination is a distinctive red, making it easy to read.

One thing I have noticed, however, is that ambient room illumination tends to reflect in the display, somewhat obscuring critical information. Sometimes a shade is required when making very careful measurements.

A feature for our future is a front panel-mounted probe jack. It is designed for a x10 probe and will be very useful in detailed troubleshooting when equipment fails. On the other hand, I am concerned that because it is limited to 10 volts DC plus signal, some care may be needed when testing failed circuits. A faulty component could easily put 12 V where you least expect it.

Incidentally, the same caution exists for the regular A and B inputs, because they are limited to a total level of an 8 volt signal plus DC.

For all of the above reasons, we are thor-

oughly pleased with the Philips waveform/vector monitor. It is an easy-to-use piece of test equipment that makes you feel equally at home, whether you are an beginning operator or a skilled engineer. This is an important condition if true quality control is to be enforced. ■

Editor's note: Robert Peirce has more than 20 years' experience in both commercial and public broadcasting, as well as in cable television, studio production and post production. Currently, he is a manager of the Boston Chapter of the SMPTE.

The opinions expressed above are the author's alone. For further information, contact Philips TV Test Equipment in Europe (Telephone: +45-32885-911; FAX: +45-434323-90), or circle Reader Service 135.

The First Two Names in Digital Audio for Video...

BUYERS BRIEF

The VM771 Video Master by FM Systems Inc. is a baseband video processor that stabilizes video levels, clamps out low frequency interference, and automatically corrects Luminance-to-Chrominance Inequality.

The VM771 input level operating range is 0.5 to 2.0 Volts peak-to-peak. Within this input range the VM771 will control sync level, white level, output video level, luminance-to-chrominance and back porch clamping at the output.

In addition, this Video Master insures constant standard video signals even though video from a multitude of variable level sources are used. This helps to insure correct CATV Scrambler operation and video recording levels.

Condor Flies High with H-P

Quality Advisor Helps Post Facility Correct Illegal Colors Without Clipping

by Ab Weber
Director of Engineering
Condor Broadcast

AMSTERDAM

Condor Broadcast is a high-end facilities house that is primarily engaged in post-production of television commercials. We recently purchased two Hewlett-Packard

which is unacceptable for commercials. If the color of a product changes between post-production and the final broadcast, there will almost certainly be a claim for a free rebroadcast of the commercial. One such claim can be more expensive than the cost of a Quality Advisor, and it certainly would not help our reputation as a high end post production facility.

recording. It is a much safer and more convenient way of keeping colors legal than constantly checking a waveform monitor/vectorscope through a digital/analog converter and encoder. The editors concentrate only on the program and do not waste time with the technical aspects of the video. Also, there are no more discussions with producers about why colors cannot be as saturated as they can be on the Henry.

GOOD ADVICE

The Quality Advisor also has a number of other features that make it an attractive addition to our facility. It gives us the ability to see 4:2:2 digital video in 10-bit or 8-bit YCrCb format, and pixel values may also be displayed in RGB, composite magnitude or phase formats.

It also allows us to retain contrast in the video by using soft and hard color limits with an adjustable gain slope, and it has a preset function to customize settings at the touch of a button. There is also a nine-pin mouse port for use with a component monitor.

In all, we have found the Quality Advisor to be a valuable piece of equipment at our facility. ■

Editor's note: Ab Weber has worked at Condor for the past five years, having formerly worked at Ampex and RTL Holland. He is a member of the Dutch Guild for TV Engineers.

The opinions expressed above are the author's alone. For further information on the Quality Advisor, contact Hewlett-Packard in the U.S. (Telephone: +1-408-553-3891; FAX: +1-408-553-3905), or circle Reader Service 45.

The Hewlett-Packard Quality Advisor

Quality Advisors.

The reason we looked into the HP Quality Advisor is because of the problems we were having with illegal colors. Traditional methods of monitoring with a waveform monitor were not being used carefully by our editors and interfered with their need to concentrate on the program.

LEGAL TROUBLE

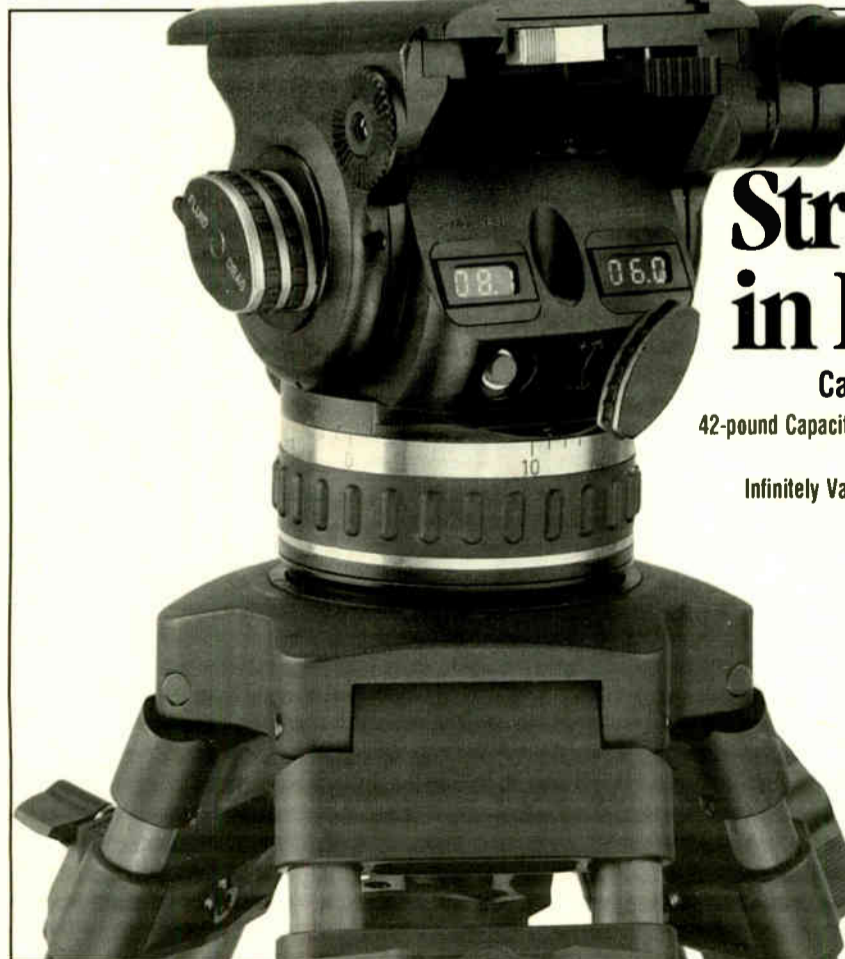

Illegal colors were causing two problems: the subcarrier was either going below -200 mV, which might disturb the synchronization of the picture, or the subcarrier was going above 800 mV causing it to go into clip.

This clipping can cause a color change

We decided to buy two HP Quality Advisors, one for each of our Henry suites. The units are connected between the Henry output and the monitor/recorder

The Quality Advisor can operate in two modes. It can display the illegal colors as an overlay on the picture using a separate monitor, or it can automatically correct the illegal colors by reducing saturation, not clipping. We chose to use the automatic correction so that the editors can concentrate on the creative, not the technical.

In this way, the producer is simply limited to making only legal colors. Any illegal colors that would be produced by the Henry are now automatically corrected before

Strength in Numbers.

Cartoni's new Delta with Digital Displays.

- 42-pound Capacity. Ideal for dockable camcorders with large battery packs and fully rigged EFP cameras.
- Infinitely Variable Counterbalance. Balances offset payloads such as long lenses & top-mounted viewfinders.
- 10 Basic & 40+ Intermediate Fluid Drag & Tilt Settings. Patented fluid damping module yields consistent drag & ultra smooth camera movement throughout the range.
- 2 Digital Displays. LED readouts indicate counterbalance and tilt drag values for optimum repeatability.

BUYERS BRIEFS

Tally Display Corp.'s interactive display system can be interfaced with virtually any routing switcher to provide automatic and instantaneous source identification and tally status. The system provides source error detection and status on a system-wide basis.

The system offers nine different display modes, as well as 18, 13 and dual nine-character, one-piece display modules for different system applications. Each display module contains an advanced microprocessor and a digital clock that can read time code.

All source identification, status indication and messages are user programmable and automatically updated.

For more information circle Reader Service 68.

Tentel introduces the all new TSH-B8 to its family of test instruments. The TSH-B8 is a multifunction SP reference plane gauge, which is not available on any factory gauges. It operates with the large SP machines, and can be used to measure the heights of the small cassette mounting posts. Also, it can be used to measure the heights and perpendicularity of the reel tables relative to the cassette reference plane.

The special indicator included with the TSH-B8, is calibrated directly in tenths of millimeters. The measurements performed with this new gauge prevent tape oxide shedding, which causes video drop outs and other problems.

For more information, circle Reader Service 66.

Wohler's Multiple Source Metering System is used for monitoring and testing the quality of broadcast audio signals in TV facilities. Available in one and two rack units, the system features from one to 20 audio sources that can be monitored in a one 19" rack space.

In addition, the system displays from one to 10 AES/EBU stereo channels. Also, eight user-selectable display modes from standard PPM and VU to PPM over VU, and six more useful modes are provided. Other features include an expanded scale mode for precise level setting and a range of 90dB.

For further information, circle Reader Service 34.

The Videotek VTM-100 is a single-rack unit, menu-driven, rasterizing waveform monitor/vectorscope featuring stereo audio level indication.

All functions are selected from a drop-down menu system, accessible via the unit's joystick, or by mouse or remote control.

Limits can be set to user requirements, and portions of waveforms that exceed levels are displayed in a different color.

For further information, circle Reader Service 65.

USER REPORT

Dorrrough Keeps WFRV in Form

by Dan Ullmer
Chief Engineer
WFRV-TV

GREEN BAY, Wisconsin

For years I have been watching for a cost-effective and easy-to-use alternative to the standard video waveform monitor. At WFRV, many of our operators do not understand how to read the video waveform monitor well. And others are too busy keeping up with everything else to interpret a standard waveform display as often as they should.

In addition, waveform monitors are expensive. I have tried two video display-type waveform monitors in which the display is viewed on a video monitor. These have the advantage of being less expensive, but are just as difficult to interpret. Also, seeing is very difficult when viewing the white flag in the VITS signal for peak white.

THE SOLUTION

I have recently acquired the Dorrough Electronics composite video luminance meter model VM-40. Fortunately, this product offers a unique solution to the problem. Instead of a video display, it uses 40 bright LEDs to display the information in a clear and interpretive manner. Therefore, it should not take more than five minutes to train any operator.

It costs only US\$750, can be read even at a 20-foot distance, and has no front knobs or controls needing adjustment. A built-in alarm

feature with contact closures can be set up to alert the operator or engineer if critical video setups are violated, plus the unit is small and can mount easily above a video monitor.

Another great feature is the capability of setting up the unit to display the white flag in the VITS (vertical interval timing signal). The white flag is a test signal representing the intended 100 percent white level. When the VM-40 video meter is set up to include the VITS signal with an internal dip switch setting, the white flag will light a steady bright LED, which clearly shows the intended video level. Setting up the correct level is very easy using this flag signal.

This feature eliminates the mistake some operators make when they incorrectly increase the video level during those dark network soap operas. This procedure of using the white flag takes all the guess-work out. You may not like the levels they are sending you, but at least you know it is what they intended.

A good idea is to provide the graphic artist with these meters to keep their levels on track. Camera iris levels, edit benches, ENG vans, transmitter video alarm and STL/TSL monitoring are just a few other suggestions.

HOW IT WORKS

The unit works by separating the video into its component parts and sampling it for various level information. This information is analyzed by a microcomputer, interpreted and fed to a display consisting of a color-coded 40-segment LED bar graph.

Sync level, average video level and peak level are all clearly visible. And two separate LEDs indicate if there is proper sync and if setup level is between 4 IRE and 7.5 IRE. The display is very simple and uncluttered, presenting the desired information in a very straight-forward manner.

The Dorrough VM-40 video meter can be just the right tool for many video level monitoring applications where price, high visibility and easy interpretation are important. The unit is not designed to replace waveform monitors in technical positions, but to augment them or provide signal

monitoring to less expert operators.

One feature that it needs is a chroma level meter, but I understand that the factory is working on a design. If it is laid out as well as the VM-40 video meter, it will be an effective product and a great complement to the unit. ■

Editor's note: Dan Ullmer started his career as an audio/visual technician at Northeast Wisconsin Technical College in 1976. In 1981, he entered television broadcasting at WFRV as an operations engineer and worked his way up as an ENG engineer, studio technical supervisor, manager of engineering, and finally chief engineer.

The opinions expressed above are the author's alone. For further information, contact Dorrough Electronics in the U.S. (Telephone: +1-818-998-2824; FAX: +1-818-998-1507), or circle Reader Service 21.

AAVS Is Sound Support At France 3 Normandie

by Norbert Chaux
Technical Manager
France 3 Normandie

ROUEN, France

France 3 Normandie is a French regional channel that features broadcasts from our national network. We operate two stations; one in Rouen and another in Caen.

We offer daily information broadcasts from 12:00 to 12:45 p.m., regional news from 7:07 to 7:31 p.m. and full image reporting from 7:55 to 7:58 p.m.

We are equipped with a videocopy system comprised of an MA12 audio monitor plus associated equipment from Audio Visuel Systèmes (AVS). In fact, AVS has supplied almost all the equipment for our videocopy operations, and the entire package is installed in a single 19-inch rack.

The MA12 is coupled to an AVS 8 audio input selector type S194 controlled by an AVS video selector type S193C.

The reason I selected AVS was the fact that the company provided good sound quality and could integrate its systems in a very small space.

From the very start, AVS designed its system to fit in a 19-inch rack, and that includes a 20-segment bargraph and a

volume selector on the front panel. The bargraph has three operating modes: VU-meter, peak meter or high resolution VU-meter, all selectable from the front panel.

My selection was also influenced by its wooden package, which enables high quality acoustics. AVS also protects the sound quality coming from the loudspeakers through the use of magnetic shielding, a limiter and the unit's 10W amplifier.

Included in the MA12 features are stereo signal-phase monitoring and either front panel control or remote control, including the ability to lower the volume or cut it off completely.

In all, we have found AVS to provide a superior product backed by a solid service and support system. ■

Editor's Note: Norbert Chaux began working at France 3 Normandie in 1975 following professional training at the Institut National de l'Audiovisuel, the French TV and broadcast organization. He began his career as a video technician and in a short time was promoted to technical manager responsible for maintenance.

For further information on the MA12, contact AAVS in France (Telephone: +33-4857-2164; FAX: +33-4857-3358), or circle Reader Service 83.

Quality is Affordable

The BR-S800E/BR-S500E Editing VCRs and RM-G800U Edit Controller offer high performance, low cost S-VHS editing; joining the world-standard JVC professional camcorder, monitor and 22 Series S-VHS line-up.

This editing system is easy to understand, fast to operate and dependable. In concert with extremely creative desktop video systems, the 800 Series is the cost-effective professional option. The system fits right into the demands of traditional video editing with industry standard interfaces and features.

Edit your own program. CTL time code, recorded after shooting, makes inserting shots from any original tape frame-accurate without wasting a master audio track. Dial up edit points by exact frame number or set while viewing. Visible search is a super-fast 32x thanks to heavy-duty tapes drives inspired by the 22 Series. Edit on Audio tracks 1 and 2 together or separately. Audio tracks 3 and 4 are CD quality Hi-fi tracks.

The edit controller can trigger a second playback vcr and desktop switcher for A/B effect transitions between two source tapes. You can integrate with the top-range 22 Series via plug-in expander cards for RS-422 control, parallel control, digital noise reduction, and VITC/LTC time code, or even with an entry-level vcr like the BR-S368E.

Build your own application. Tailor-make your own business video application by plugging in your computer with the RS-232C card.

JVC professional products are not only well-accepted—they set new standards for performance.

PRODUCTION VALUES

Video Invades Presentation Market

Specialty Productions Are On the Rise As Manufacturers Compete for Attention

by Frank Kelly

Visit any convention center in a major city and you will likely find a trade show or industry-specific exhibition in progress. They always feature row after row of product exhibits from various companies hawking their wares. These companies go to great lengths (and expense) to make sure their products are noticed in the din and confusion. It is not unheard of to spend US\$50,000 or more on booth design alone, not to mention the expense associated with renting display space from the promoters of the event. The glitz factor is substantial, at times employing professional exhibit "performers" and sophisticated video walls and computer multimedia displays.

All this effort and expense is put forth in the hope that bewildered attendees sporting name tags and clutching free samples will break away from the pack long enough to gather product brochures or other logo-embossed gizmos. Any tactic is fair game in this battle for attention.

It only takes a single bad showing to make a company keenly aware of how effectively video and computer technology can be used in this fiercely competitive arena. The stakes are high if you consider that trade show pre-orders are often the guide for further product development.

PRODUCTION SPECIALS

This exhibit frenzy has created an opportunity for video professionals who "specialize" in productions for use in trade shows. This new breed should be well versed in both computer and video technology.

Not too many years ago, trade show presentation was a field dominated by the slide show, and this concept has been extended recently to include computer displays that shuffle stills and play sound files. Today, slides are quickly being replaced by polished video productions displaying a combination of computer and video techniques specifically designed to grab people's attention.

I have coined the phrase "concept video" to refer to this category of production. It is more descriptive than calling it a "loop tape" — a term widely used to describe how a video is replayed continuously. Concept videos differ greatly from the traditional loop in that they offer the opportunity to break away from the methods usually associated with standard linear production formats.

Traditionally, scripting calls for the creation of a beginning, middle and end to tell the story of a product. However, there is a fundamental flaw in this methodology when producing a video for a trade show: people rarely watch the production from beginning to end. Writing and producing the concept video is an entirely different

process that calls for scripting all salient points of interest into a series of successive "middles." This allows for presentation in abbreviated form of factual material that can be quickly absorbed.

With skillful writing, you can repackage the primary points of interest in a number of ways and use alternate visuals for their respective video elements. For this to be effective, rapid-fire edits and brief narratives are a must. Anyone paying close attention to the entire production will see the similarities between each segment.

Also, other elements need to be inserted between these middles. I find that testimonials are quite useful and, when properly edited, they can have the effect of counterbalancing the "high tech" aspect of the production.

In many respects, this format is similar to the classic slide show. Usually, a script is written for a narration that, once recorded,

is used as a guideline to insert corresponding visual elements. But unlike the slide show or its computer-generated counterparts, the concept video usually integrates computer and video technologies in new and innovative ways. Three-dimensional modeling and animation are used to convey ideas or products that do not yet exist in the real world or are too expensive or difficult to capture with conventional video acquisition.

MAKING MODELS

While this is certainly not a new production method, there are recent technological advances that make modeling and animation software easier to grasp and much more affordable than ever before.

Just about anyone can buy off-the-shelf software that will allow them to create 3-D animations of the client's logo. NewTek

Circle 119 On Reader Service Card

CONTINUED FROM PAGE 45

Presentation Market Matures

(Reader Service 57) has recently released the multi-platform version of its LightWave 3D software. Another example is Crystal Graphics' TOPAS Professional version 5.1 (Reader Service 29), which includes matched perspective and interactive lighting for rotoscoping 3-D animated objects that appear to interact realistically with pre-produced video backgrounds.

Throw in the Personal Animation Recorder from Digital Processing Systems (Reader Service 90) and those animations can be played out to video directly from a

hard disk. These and other options are making experimentation and innovation more likely.

Generally speaking, the use of animation is fast becoming a standard component for trade show videos. However, at times the only materials available will be still photos. I cannot stress the importance of creating some kind of movement with these still elements. This is where a good copy stand camera and access to either a motion control rig or DVE (Digital Video Effects device) can pay

big dividends.

Slides that contain text or diagrams do not usually transfer well to video when shot from projected screens or captured with transfer devices that contain their own CCDs. I have found it is best to have prints made from the slides and shoot the prints from a copy stand.

To make the best use of still images with a copy stand, you should invest in the appropriate lens. I highly recommend Century Optics (Reader Service 104) and its diopter series for existing lenses. I have

a camera with a Canon 15x1 lens that was designed for location work. I was able to dramatically increase its zoom range in close-ups with one of these attachments.

Several methods can be used to add movement to still images, such as using slow zooms and pans with the camera, or using a DVE to accomplish digitally many of the same effects that would normally require a motion control camera rig.

It is important to remember that these elements will usually be on-screen for only a few seconds and perhaps re-used in multiple segments. Several versions of each camera movement, with different pacing, should be captured to tape for later editing. Make an exact duplicate of this work reel for A/B-roll effects.

CRAZY WITH EFFECTS

In almost every other production format, I am firmly against the use of DVE moves unless absolutely necessary — they distract from the message being delivered. However, a trade show concept video is a dramatic departure from this philosophy. In fact, it is practically a license to go crazy with effects.

Visual impact is vitally important to attract attention from people passing by a trade show stand. After all, this is not "Masterpiece Theatre." Your imagery has to compete with a tremendous amount of visual stimulus. Big fonts, flashy effects and background music with a fast tempo and a "non-descript" beginning and end are the order of the day.

**Not too many years ago,
trade show presentation
was a field dominated by
the slide show...**

The final step is to create the work dub for the show itself. Remember the concept of several middles? Here is where it really pays off.

Let's say that you have created three separate two-minute segments that are similar in content but different in execution. Take some other elements that complement the main concept (such as testimonials or multiple versions of animated logo graphics) and insert them in somewhat random order in between the three segments. Make at least three different groupings, and then edit this sequence so that there are no gaps between the individual segments. Then insert the looped music bed on one of your audio tracks. Your final tape that goes to the show itself should be a short length that will recycle in automatic playback units quickly. (A brief pause in the playback sequence every 15 minutes or so is acceptable.)

While budgets for these kinds of productions are always dictated by the amount of work involved, it is important to remember that the usual cost to produce such an effort should be tempered with the knowledge that it will probably require frequent updates. Bid your work based on that principle and you will find clients more than willing to plan ahead for future productions on a regular basis. ■

Frank Kelly is the owner and operator of Spot Ad Productions in San Jose, California, a production company for commercials and industrial projects.

The Agile Omni Global VU option gives you one touch access to all satellite formats.

More channels, more signals, more frequencies — life in the down link is becoming more complex every day.

What you need is something to simplify your life.

What you need is the Global VU Model CAM830 Control Access Monitor from Standard Communications.

Direct or remote control.

Used in conjunction with the Agile Omni receiver, the Global VU gives you simplified access to all satellite formats from easy front-panel controls or from a PC comfortably situated on your desk, miles away.

Directly or using the straightforward Windows-based software, the CAM830 lets you add or modify formats, then scan them by RF frequency and/or audio subcarrier. It gives you complete control over all three audio

subcarrier demodulators, as well as international video features such as PAL, SECAM and NTSC. It gives you control of video and audio output levels with individual channel memory.

And we're just getting started.

Spectrum analysis.

Want to really see what's going on? The Global VU gives you a screen-filling display of the RF spectrum for each satellite on your remote PC. It also gives you a real-time look at the C/N ratio without any time-consuming precalibration.

And there's more. As a field retrofit or optional add-on, the CAM830 gives your Agile Omni more easy-to-use control than you may have ever thought possible. To get the full story fast, including complete specifications, fax Standard today at 800/722-2329

(California and International numbers, 310/532-0397) and we'll fax it right back to you.

Be a know-it-all. Get your hands on a Global VU.

Apple Initiates Mac Licensing

by Tony Reveaux

CUPERTINO, California

For many months this summer, rumors flew that Apple Computer was in financial trouble and might be bought out by AT&T or a Japanese firm or possibly even go out of business. Recent news is much more promising, however.

Instead of a platform-specific dead end, Apple is opting for a collaborative alliance with IBM and Motorola and is allowing the licensing of the Macintosh operating system (OS) to other manufacturers. This evolution will have widespread benefits for users on both sides of the Apple/IBM picket fence, especially in multimedia and digital video.

Apple's groundwork for this collaboration has been its RISC-based Mac OS. Also, IBM — reeling from the Intel threat — has

warmed up considerably to the idea. Its goal is to forge a Common Hardware Platform (CHP) where "... users can have one computer and yet take advantage of tens of thousands of applications designed for different operating systems."

The high-performance Peripheral Component Interface (PCI) bus planned for next year will have a large impact on a joint IBM/Mac operating system, said Jim Gable, product line manager for Power Macintosh.

"In multimedia, you are doing so many things that require large bandwidth across I/O devices, and so we need digital video cards that can move data at vastly faster speeds than we can on NuBus today," he said. "(With the PCI) you will be able to do capture and printing to tape at a higher quality without such expensive cards."

In addition, a manufacturer of PCI expansion

cards can easily configure it to run in Macintosh or PC mode, so there will no longer be such a great chasm between the two sides of the market.

Right now, Power Macintosh is about 25 percent of Apple's sales, and Gable expects that a year from now it will be at least 50 and perhaps even closer to 75 percent. The goal for 1994 was to establish the RISC PowerPC — to show its compatibility, demo plenty of native applications and create confidence that it could feel just like a Macintosh.

So far, 600,000 PowerPC units have been sold, making Apple the largest-selling vendor of RISC-based personal computers.

"In 1995, our big chore is to make PowerPC much more high-volume and

move it to our lower price points and to PowerBooks," Gable said. "We are the first to take the RISC chip, which used to be in workstations, and move it to a PC but make it something that you can still recognize as easy to use. Mac OS has really laid the groundwork for open licensing where other people can sell Macintosh computers."

Apple, IBM and Motorola plan to collaborate with other vendors on porting their operating systems to the new CHP platform, which will include scalable designs for the PCI bus, a system boot that works independently of the operating systems, and industry-standard components and I/O systems for compatibility.

Initially the CHP platform will support Mac OS, OS/2 for the PowerPC, AIX, Microsoft Windows NT and Novell. It will do so with both a Mac system ROM and a PC ROM BIOS. ■

USER REPORT

DP/Max Makes Its Mark at ACME Photo

by Tim Davies

Editor/Designer
ACME Photo Video

SYDNEY, Australia

The DP/Max graphics workstation from Dynatech was the unsung hero of a recent 30-second Mitsubishi DIVA commercial that ACME Photo Video post-produced for the Japanese market.

ACME's client list includes virtually all of our region's top agencies, including Saatchi & Saatchi, McCann Erickson, Lintas, Young & Rubicam, with commissions from far flung offices, such as Tokyo, Singapore, Jakarta, Beijing, as well as the Australian capital cities.

ONE AND ONLY

For the DIVA project, it is my belief that the DP/Max is the only graphics workstation that could have achieved the desired effects at one time because of the multiple variety of software options it offers. In fact, I have found the DP/Max to be the most complete graphics, animation and effects tool I have experienced.

In my opinion, the DP/Max is a very under-rated device. We have yet to see a project come through our facility that the Max has not been able to handle. And now with the ability to fall back on Silicon Graphics Inc. as well, we are turning out some exciting stuff.

What made the DIVA commercial story board so interesting was that it depicted a temple with live-action futuristic people dressed in white gowns with stairs that extended higher and higher into infinity disappearing into clouds.

The live-action sequence was filmed with an ARRI SR16mm on the steps of Sydney Opera House with nine actors. Using locked-off reframing of the shot, they were multiplied into more than 40 people.

The set-up at ACME offers both on-line and off-line facilities in addition to Sony Betacam SP video and Arri 16mm film cameras. The off-line configuration includes three linear Betacam SP suites with Shotlister, as well as Avid and

DVision non-linear suites.

In deciding how to handle post production for the DIVA spot, we chose the DP/Max to completely re-design the visual frame by rotoscoping the actors to execute the necessary compositing. We then had to drop out the Sydney skyline and replace it with perspex temple columns and matte in a new clouds background. The project was so complex that we logged nearly 80 hours in post production.

QUEST FOR PERFECTION

At ACME, we have something of an obsession with hi-tech equipment, and it has brought us a reputation for perfection. We would like to become world leaders in the highly specialized art of video-to-film transfers.

Utilizing Silicon Graphics hardware and image enhancement software designed in-house, we can take a television commercial finished on video and produce a 35mm film version for cinema release. The image quality product is as close to 35mm original as can be obtained from video. Tested against our competitors in the U.K. and U.S., our end results were found to be their equal.

We decided to acquire the DP/Max after clients kept urging us to adopt more of a graphics-based animation system. We carefully examined other systems, but none had quite the range of software options as the DP/Max. We now look at ourselves as a special effects design suite, not an on-line edit suite. ■

Editor's note: After starting on the Paintbox at 16, Tim Davies worked his way up through the ranks to become senior graphics and FX artist at ACME in 1991.

The opinions expressed above are the author's alone. For further information on the DP/MAX, contact The Dynatech Group in the U.S. (Telephone: +1-801-328-8872; FAX: +1-801-328-3669); in Asia (Telephone: +852-868-1993; FAX: +852-525-8297); in Europe (Telephone: +44-635-521-939; FAX: +44-635-528-387), or circle Reader Service 103.

ON GOOD TERMS

Selecting the Right Format

by John Spofford

Targa? PCX? TIFF and GIF? The sheer number of computer image formats is confusing. We have seen little standardization, and because most of today's facilities are multi-platform, there are literally dozens of image formats to deal with.

ONE OR THE OTHER

2-D image formats fall into two broad categories: bitmaps (or raster graphics) and vector graphics. Bitmaps are pictures that are created with pixels (picture elements) or the tiny individual blocks of color that create an image on a computer screen. Bitmapped images are relatively easy to convert from one format to another, although an additional worry is whether the pixels are rectangles or squares.

Vector graphics, while displayed on the computer screen as a bitmap, are actually defined by the computer as a series of points, lines (vectors), angles and other mathematical relationships. Vector graphics are more complex than the computer screen suggests, making it difficult to translate to another vector or bitmapped image format. A hybrid type of graphics file, known as a metafile, has been developed to remedy this. Metafiles include bitmapped data in addition to their mathematical information, making vector graphics information portable between applications.

What follows are a few of the more com-

mon 2-D still image and animation formats. These tend to be the most "portable" formats — formats that are easily moved between different applications or computer platforms.

ALIAS — This is a 24-bit image format used by Alias Research for rendered images from Alias Animator, a high-end 3-D rendering package.

ANIM — ANIM OPT 5 is the most common Amiga animation format and is actually a series of Amiga IFF still images compressed into a single large file. ANIM OPT 7 and 8 are newer variations that take advantage of 32-bit memory in more advanced Amigas.

AVI (Audio/Video Interleaved) — AVI is the animation format of Microsoft's Video For Windows. Similar to Apple's QuickTime format, digitized or computer-generated video frames and synchronized audio are interleaved into a single computer file. AVI clips are played back on Windows-equipped PCs and are generally independent of screen resolution and palette.

BMP — BMP was created by Microsoft as a simple bitmap format for Microsoft Windows. The Windows bitmap format supports monochrome, 16 colors, 256 colors and 24-bit color. BMPs are actually a subset of the Windows DIB format and do not support image compression.

DIB (Microsoft Windows Device Independent Bitmap) — A DIB is able to handle up to 24 bits of data (16 million colors) independent of the computer's display card. DIB images support monochrome, 16 colors, 256 colors and 24-bit color.

EPS (Encapsulated PostScript) — PostScript is a typesetting and page description language defined and trademarked by Adobe Systems Inc. PostScript information is normally sent directly to a PostScript-compatible printer. An Encapsulated PostScript file is a postscript description in a portable format that can be loaded into another graphics software application.

FLI/FLC — Often referred to as "flicks," these animation files were created by Autodesk for use on the PC. They are similar to the Amiga ANIM format and consist of a series of sequential images compressed into a single file.

FRAMESTORE — A 16 million color bitmap format developed by NewTek for the Video Toaster. A Framestore is the stored contents of a Video Toaster image buffer. The latest version of the Framestore format supports image compression.

HPGL (Hewlett Packard Graphics Language) — A vector-based image format most commonly associated with output to pen plotters.

GEM — A vector graphics metafile developed by Digital Research.

GIF (Graphics Interchange Format) — A popular bitmap format created by CompuServe. GIF supports color images with palettes ranging from two to 256 colors. There are currently two GIF subsets; 87a and 89a. GIF files, at least in their most generic forms, are extremely well supported across various personal computer and UNIX platforms.

ICO — The ICO format represents icons from Microsoft Windows. Icons are always 16-color bitmaps measuring 32 x 32 pixels.

IFF (Interchange File Format) — IFF is the standard Amiga bitmap image format. Established by Electronic Arts and Commodore in 1986, all Amiga graphics applications support IFF.

INFO — An infor file is an Amiga icon. It contains some information about the file it represents as well as bitmap data for the icon. The icon bitmap is typically two to 256 colors, with no size limitations.

JPEG (Joint Photographic Experts Group; common extensions are .JPG, .JPEG, .JFIF) — JPEG is a compression scheme designed to greatly reduce the size of 16 million color images and is capable of compression rates of 75:1 or greater. It achieves this by throwing away image data through "lossy compression."

LZW (Lempel, Ziv & Welch) — Not an image format but a method of image file compression. LZW encoding is a very effi-

cient technique that analyzes color patterns within an image: If a pattern recurs, it is encoded in an extremely simple form.

MacPaint — A monochrome (black & white) bitmap format used by the original two-bitplane Macintosh paint program.

PICT (other common extensions, .PCT, .PIC) — Probably the most common Macintosh color bitmap format. Supports monochrome, 16 colors, 256 colors and 24-bit color.

PCX — The PCX format was originally developed by Zsoft Corp. for its various painting packages. PCX supports monochrome, 16 colors, 256 colors with gray palette, 256 colors and 24-bit color.

RLE (Run-Length Encoding) — Yet another method of image file compression. This type of encoding is very quick and yields good results when an image has many runs of the same color pixels. RLE compression is an option for DIB, Targa and TIFF image files.

SGI RGB — A bitmapped image format native to Silicon Graphics workstations.

SUNRASTER — An bitmapped image format developed by Sun Microsystems for use in its line of UNIX workstations.

TGA, TARGA — The Targa format was originally developed for use with Truevision Targa/Vista graphics boards. There are several variations, including simple black & white and color-mapped images, as well as the more common 16/24/32-bit formats. Images may be either uncompressed or RLE encoded. The Targa file structure is relatively simple and is an extremely reliable format for transfer between different computer platforms.

TIFF (Tagged Image File Format) — A popular format used on both the Macintosh and PC platforms. The TIFF format is probably the most versatile in general use.

The well-known drawback to the TIFF format is its complexity. For example, TIFF files created by a PC will have a different byte order than those intended for a Mac. Better graphics packages will save a TIFF either way. Some graphics programs do not follow every detail of the specification and create TIFF files that are less than 100 percent compatible. TIFF supports image depths of 1, 8 and 24 bits. It handles monochrome, greyscale, pseudo-color, color mapped, true color RGB, CMY or CMYK.

QUICKTIME — QuickTime is Apple's animation standard for the Macintosh. With appropriate drivers, QuickTime can also be played on Windows-equipped PCs. Moving video and synchronized audio is interleaved into a portable computer file. QuickTime "Movies" are hardware independent and will play on any color-capable Macintosh. This technology is the basis of many Macintosh non-linear editing systems.

WMF (Windows Metafile Format) — A vector graphics metafile developed for Microsoft's Windows.

X — A bitmap format developed for X Windows. X Windows is a Graphic User Interface (GUI) developed for the UNIX operating system.

USER REPORT

Avid Fills Role at Tele-Cine

by David Pollard
Head of Post Production
The Tele-Cine Cell Group

LONDON

The Tele-Cine Cell Group was one of the first companies in Europe to purchase Avid Technology's Media Recorder Telecine digitizing station shortly after its launch last September.

Our aim was to make Tele-Cine a one-stop shop for post production. We already had a collection of Avid equipment, namely four Film Composers and a top-of-the-line Avid AudioVision. We are also a beta test site for the Open Media Framework (OMF) interchange. You could say that the addition of Avid's Media Recorder Telecine was the final brick in the wall in terms of equipment.

Media Recorder Telecine is a digitizing station that resides in the telecine bay to capture film dailies directly to disk during film-to-tape transfer. It automates and speeds up the process of moving from telecine to off-line editing by eliminating the additional step of digitizing material to hard disk after transferring film to tape. Once the telecine process is complete, we can immediately deliver drives containing Avid Media Composer or Film Composer bins and media files to our clients, allowing editors working on Avid systems to begin editing as soon as the transfer has been completed.

Tele-Cine offers a family of compatible, disk-based systems that streamlines the film transfer process and the logging of dailies. We also provide true 24 frames-per-second editing, pre-visualization of effects and frame-accurate cut lists. Our goal is to provide digital solutions to seamlessly integrate the entire post production process for projects such as feature films and television programs.

During the telecine transfer process, Media Recorder Telecine automatically reads, captures and stores to disk all information used to describe the relationship between the actual film negative and the frames that exist on videotape, including film edgecode, videotape timecode, audio timecode and the film's pull-down indication. In addition, it automatically builds film bins and organizes information during digitizing, resulting in faster, more accurate and less labor-intensive editing preparation.

During the digitizing process, Media Recorder Telecine decodes up to three lines of Vertical Interval Time Code (VITC), a new proposal presented to SMPTE last Fall by Aaton and Evertz. VITC contains information on two time-codes, a full keynumber and user-bit data. Media Recorder Telecine also supports LTC and, in addition to timecode, the unit supports all

frame rates, as well as all Avid video resolutions.

Burn-in functionality is available for all six fields of information and is stored in the system's database for future list generation. All settings can be saved in user files to allow quick access to different configurations. The system can operate in either slave mode or master mode. When operating in

slave mode, the telecine edit controller controls the digitizing process. When operating in master control, the Media Recorder controls the digitizing process.

Media Recorder Telecine includes a Macintosh Quadra 950 with 29 MB of RAM, a 230 MB internal hard drive, a 17-inch, two-stage monitor for viewing the digitizing process and controlling set-

tings, an audio A-D/D-A converter, an audio co-processor (SA4), a video slave driver, a NuVista Plus video interface card, and Avid Enhancement board, documentation (user and hardware guides), and the Avid Media Reader for reading timecode. Storage and additional video monitors are supplied by the user.

We are now looking at networking our entire range of post production systems using the OMF interchange and Avid's networking architecture. This will enable us to offer a totally integrated professional post production solution where customers can

telecine to digital tape and disk simultaneously, edit on Film Composer, track-lay in AudioVision and dub in our AMS Logic theaters, moving digital files between each process over a network. ■

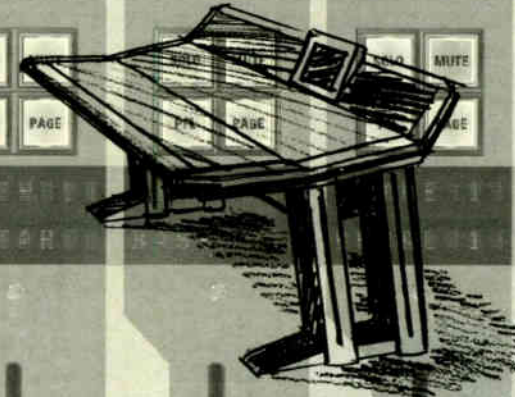

Editor's note: David Pollard is responsible for The Tele-Cine Group's post production systems.

The opinions expressed above are the author's alone. For further information on the Telecine Recorder, contact Avid in the U.K. (Telephone: +44-753-655-999; FAX: +44-753-654-999), or circle Reader Service 71.

cantus

The new fully digital mixing console system

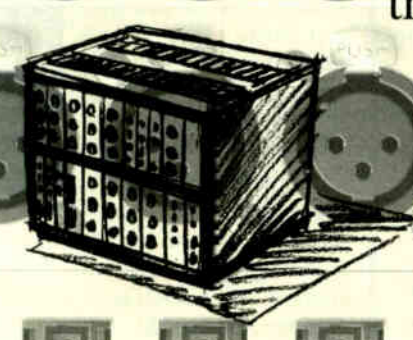

Offers flexibility due to its modular and compact console and audio signal processing, adaptability due to changeable channel configurations at any time, as well as clarity due to its well structured free assignable control surface. Complete static and dynamic automation, integration into the Nexus-System, as well as exceptional audio quality, represent an unsurpassed work tool for studio production and live recordings

nexus

The reliable fully digital switching and transmitting system for audio signals

A modular networking system consisting of a compact base unit with all different kinds of analog and digital in- and output formats, as well as its own digital signal processing capacity. Strictly bidirectional fiber optical connections keep the costs low, eliminate interferences, and build complete network systems for broadcast, audio post, music production, remote unit, theatre, and PA application.

I N P O I N T S

Desktop Systems Keep Evolving

by Bryce Button

It is that time of year again, when everything seems glossy and new. Thoughts of faster and better systems keep you up at night and keep your accountant nervous. It is also a time when people as fearless and foolish as myself try to predict the movements in the non-linear cosmos for the next 12 months — knowing full well that a year down the road these very utterances are apt to produce much laughter and tears.

FUTURE SHOCK

Here then are my thoughts on what to expect in what again is due to be a great year of change. I will also throw in highlights from a few of the many vendors competing for a line in your operating budget spreadsheet.

I will start with some of the larger issues that will more than likely affect the industry as a whole.

The steep drop in hard disk storage prices, with a corresponding increase in storage size, is sure to continue throughout 1995. This will have two major impacts. The ability to store high(er) resolution video on disk will be less of a financial obstacle. This, in turn, will let vendors feel more comfortable offering less compressed (and higher quality) images to the market

the production market to its extremes. Clients with the budgets and time restraints that keep the bigger houses busy will continue to do so. Boutique houses and freelancers with lower overhead are likely to keep up with the low-cost offerings from desktop digital vendors. The net effect is to increase personal income for employees at both big and small facilities, drawing talent away from the middle.

The maturation of media servers in the last few months, from vendors as diverse as BTS, Quantel and Avid will result in a much larger switchover in broadcast facilities to random access digital systems. The ability of digital cart systems to change a

Quantel's Clipbox can provide central storage for multiple non-linear on-line suites.

lineup at a moment's notice, without the sort of hardware wear and tear issues intrinsic to tape-based systems, will prove a big attraction.

I expect to see stronger audio features integrated into desktop systems. ImMIX now offers manual mix-

at the price points we have become accustomed to — if not even lower.

Further, the recent improvements of operating systems providing more disk partitions will allow more storage to be added to standalone and networked systems.

This increase in storage demand will, in

turn, lead to the further development, acquisition and acceptance of media file servers. Coupled with the growth of networked servers, expect to see a greater push by vendors for file-compatibility frameworks as witnessed by Avid's OMF (Open Media Framework) and ImMIX's MFE (Media File Exchange).

Numerous proprietary compression schemes will continue to irritate those who feel that what is really needed is simply no compression at all. Macintosh-based non-linear editors, who live and die by video compression, will benefit greatly from the PowerMac's change to PCI bus from NuBus technology. With three to four times the raw throughput of NuBus, the PCI's advantages are obvious.

Hard disks will not replace tape in 1995 (or any time soon). The transportability of tape and its continued use as an archival format will allow the videotape format wars to continue in parallel with developments made in digital acquisition to disk.

down on the fly with its version 1.3 software. Avid's merger with Digidesign, well-known for its digital audio editing software, is also sure to have a positive impact on Media Composer owners. Quantel's Editbox now offers 16 tracks of audio, and Nightsuite, from Amtel Systems, boasts Sadie, a system capable of 24-bit audio resolution.

The 16- to 24-month development cycle, common to this industry, suggests that we can expect news from Silicon Graphics sometime this year. This should have the effect of lowering cost barriers of Unix-based graphics workstations. You can expect Hewlett-Packard and Sun Microsystems to follow suit and make more aggressive runs at this market in the coming months.

Lastly, component I/O looks to be a definite option in any system worth its salt this year, with many systems bypassing the need for transcoders. Component video is a feature that certainly helps any compressed

WORDS AND IMAGES ON-LINE

We have been producing and marketing broadcast quality audio and video signal handling equipment and on-line character and image generation hardware since 1978. A complete range of equipment to satisfy the most varied application requirements:

- Character Generators
- Logo Generators
- Video Time Generators
- Teletext Systems
- Switchers
- Cross Point Switchers
- Distributors

We are now looking for distributors in areas not yet covered.

KEY DIGITAL EFFECTS

3-D DVEs will become the norm in the desktop non-linear market. Vendors have discovered that these features are better handled by out-board hardware integrated into their systems instead of suffering the current nightmare of rendering with software substitutes. Expect to hear the name Pinnacle Systems a lot, as numerous vendors build bridges to the Alladin Media Printer (Reader Service 25).

Development of multi-stream video for use with desktop systems will slowly bring results, allowing effects beyond a couple of layers to be achieved without resorting to further compression and rendering time.

Though the point is fiercely debated, I feel 1995 will be a tough year for mid-sized facilities. The difficulty of achieving short-term amortization, while saddled with long-term capital commitments from linear equipment, is likely to keep pushing

image look its best.

Now that we have looked at some of the larger themes at play, and realizing that nobody has a monopoly on the truth, I will now take a closer look at some specific vendor offerings. However, there are two things to keep in mind: I have not been able to include everybody I would like in this wrap-up, and it has to be realized that many vendors are not about to reveal specific details until this month's NAB show. With that in mind, onward ho.

Avid Technology (Reader Service 107) makes its first run at the PC market, announcing Media Suite Pro for Windows

The steep drop in hard disk storage prices, with a corresponding increase in storage size, is sure to continue throughout 1995.

95, Microsoft's promised 32-bit operating system. This will add to its offerings for both the Mac and Indigo platforms. The high-speed AvidNet and MediaServer products will aid those searching for a fully integrated digital facility — whether in a small boutique or a large broadcast setting.

Avid's family of broadcast products continues to grow with the acquisition of BASYS News and SofTECH Systems Inc., offering greater capabilities in newsroom automation. You can expect to see higher image resolutions and a gradual shift of the Macintosh products to the RISC-based PowerMac.

TouchVision Systems (Reader Service 116) is well into development of a new generation of PC-based products and may well have announced new releases by the time this goes to press. With an installed base of over 3,000 units, the company is experiencing rapid growth centered upon its D-Vision products for both desktop and multimedia applications.

Quantel (Reader Service 84) continues to push into the traditional on-line market with the

Though the point is fiercely debated, I feel 1995 will be a rough year for mid-sized facilities.

belief that all compression degrades images and lossless compression schemes often require more data storage than uncompressed pictures. Quantel's approach, using uncompressed CCIR-601 with the Editbox, makes it an attractive offering for higher-end facilities. Using its Clipbox technology, Quantel can achieve central shared storage for multiple non-linear on-line suites.

Matrox Video Products Group (Reader Service 100) plans to release System 3.0 for its Personal Producer product, adding non-linear capabilities with an unlimited number of video, audio and graphic layers in "near real time." Picture quality is expected to be competitive with the best systems, most of which now claim "near-Betacam quality."

For its Matrox Studio product, a Super F/X option has been made available, including Flying graphic keys and interfacing with Pinnacle's Alladin.

ImMIX (Reader Service 130) has released version 1.3 for its VideoCube and is now offering component I/O (R-Y, B-Y, Y), enabling direct interfacing to Betacam SP without outboard

transcoders. Version 1.3 allows uncompressed graphic files to be alpha-keyed over two channels of video in real time.

BATCH CAPTURING

The Media 100 from Data Translation (Reader Service 46) now has support for batch capturing from time-coded sources and offers higher image quality, bringing the product up to facility level. The company has also announced a 25 percent price reduction for its Media 100 (version 2.0), placing the price point under US\$9,000. This is within

the price range for supposed "lower-end" QuickTime-based products — a trend that should echo throughout the industry.

Night Suite (Reader Service 70) promises CCIR-601 on a machine that can cut both video and film projects. With a strong interface and a price point that begs the question "How?" this machine will get a lot of inspection when it finally hits the streets.

Lastly, NewTek Inc. (Reader Service 111) is finally shipping its Flyer editor in quantity. Initial delivery was to a few thousand

Video Toaster enthusiasts who pre-ordered and paid a deposit for their units. The Flyer only works in conjunction with a Video Toaster, which, of course, only works on the Amiga platform. The future of the Amiga has yet to be resolved, Commodore having been out of business for some 10 months. NewTek has made other platform plans, but for those we will have to wait for NAB.

There you have it. Just a sliver of what this year promises. Make sure you shop hard and long. Once you are committed to a

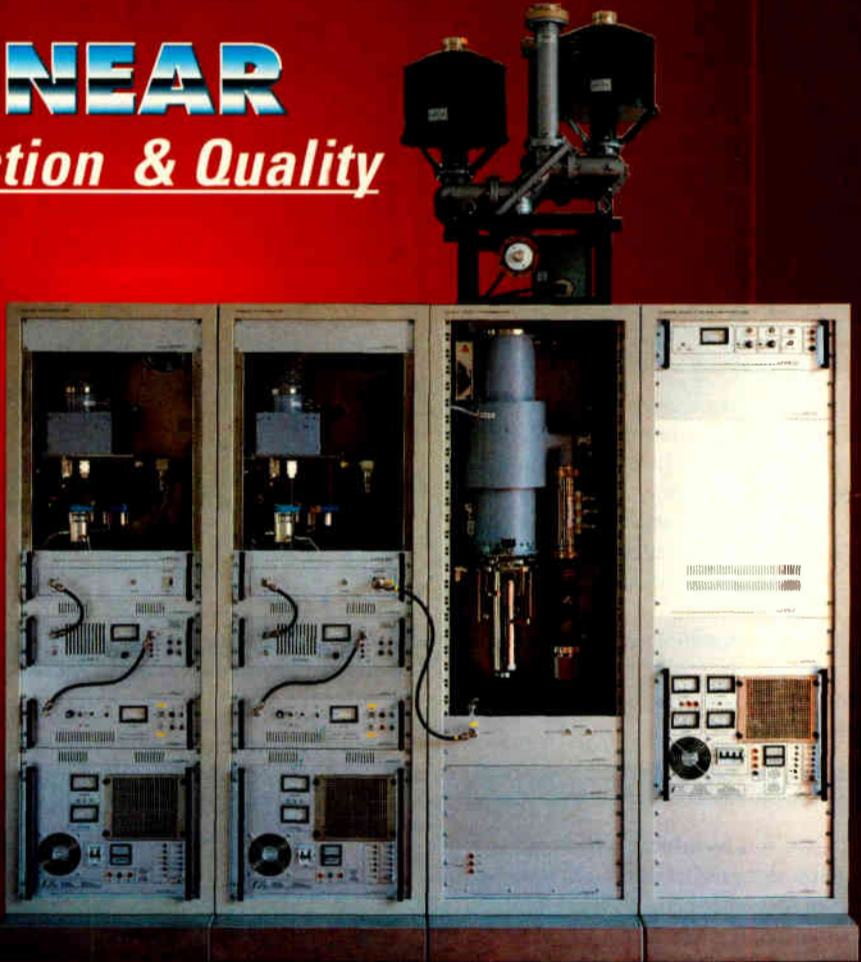

buying decision, however, you may rest well in the knowledge that the choice will be even more difficult next year. ■

Bryce Button is a non-linear editor working in the U.S. He has worked in non-linear from the first beta site days in New York City, while employed at Dennis Hayes and Associates. He is currently head of non-linear post production at Telemation in Denver, Colorado. He may be reached on Compuserve @ 72633,1603. Comments and differing opinions are accepted.

MARKETPLACE

HIGHLIGHTING THE LATEST PRODUCTS AVAILABLE TO PROFESSIONALS IN THE VIDEO INDUSTRY.

FM EXCITER

The T242 synthesized FM exciter from Iteco operates in the 87.5 to 108 MHz band and features seven plug-in ports, each of which can have a different function.

All operating commands are located on the front panel, and the transmission frequency can be either locally or remotely selected from 10 presets.

Also available is an automatic level circuit (ALC) that keeps output power within +/- 0.5 dB referred to nominal output power.

For further information, contact the company in Italy at telephone: +39-763-316265; FAX: +39-763-316239, or circle Reader Service 3.

PRESENTATION AUTOMATION

Abit Ltd. has available the Present It automation system that interfaces with air-time sales and scheduling systems for complete on-air management.

The system uses Motorola 680N0 multi-processors running Microsoft Windows and is linked by Ethernet using a proprietary real-time protocol.

Present It controls all broadcast devices on the market and features upgradeable, open architecture technology to guard against becoming obsolete.

For further information, contact the company in the U.K. at telephone: +44-71-281-3815; FAX: +44-71-281-3815, or circle Reader Service 132

TELECINE

Rank Cintel's Ursa Gold post production telecine features all-digital technology and full EMC certification to prevent interference from other systems.

Ursa Gold maintains 4:4:4 signal processing throughout, with outputs available in 4:4:4, 4:2:2:4 (8- and 10-bit), as well as analog component (YCrCb) and RGB.

Initial quantization is at 14-bit depth, allowing true digital gamma and aperture correction.

For further information, contact the com-

pany in the U.K. at telephone: +44-920-463939; FAX: +44-920-460803, or circle Reader Service 30.

DESKTOP VIDEO

Data Translation has released Ver. 2.0 of its Media 100 digital video system, now running native on Macintosh platforms.

The new version allows picture quality up to 80 kilobits per frame for NTSC and 90 kb per frame for PAL. In addition, there is a new HDR option allowing quality up to 150 kb NTSC and 180 kb PAL.

The system also features a Trim Mode that allows for greater fine-tuning of edits.

For further information, contact the company in the U.S. at telephone: +1-508-460-1600; FAX: +1-508-481-8627, or circle Reader Service 129.

COMPONENT MIXER

The DVN-400 D-1 mixer from For-A Corp. features 16/32-bit processing, 10 serial digital inputs and three key layers.

The unit features "one function, one button" operation and custom-designed ASICs for greater signal quality.

The device's four aux busses can be used for input selection to external DVEs, color correctors or other devices.

For further information, contact the company in Japan at telephone: +81-3446-3936; FAX: +81-3446-4452, or circle Reader Service 105.

INTERFACES

Thomson Broadcast has a line of interface products available for transferring signals across a range of formats.

The TTV 7770 and 7771 series of 16:9/4:3 interfaces are designed to allow existing cameras to produce in either format. The units are attached to the output of camera control systems.

In addition, the Evolution series of interfaces include distribution amps, pre-selectors and digital/analog converters, all of which can be contained in a 3RU frame.

For further information, contact the company in France at telephone: +33-3420-7000, or circle Reader Service 76.

INTERCOM SYSTEM

The DOS 3000 all-digital intercom interface system from Drake Electronics offers a range of new features designed for greater operability.

For example, the system's remote panels can be located anywhere in the world, regardless of the location of the matrix. Telephone interfaces include new DTFM dialing facilities both into and out of the system.

In addition, new control software is contained in a Windows-based package.

For further information, contact the company in the U.K. at telephone: +44-707-333856; FAX: +44-707-371266, or circle Reader Service 20.

WIDESCREEN SOFTWARE

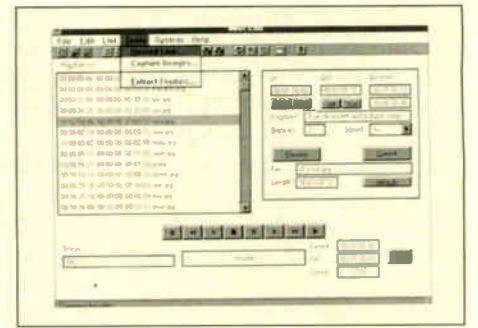

Pinnacle Systems has released new software for the Prizm digital video workstation that supports the 16:9 screen format for easier manipulation of theatrical releases.

The software also contains new refractor shapes, such as cylinders, exploding tiles, magnifying glass effects and melt-downs.

For further information, contact the company in the U.S. at telephone: +1-408-720-9669; FAX: +408-720-9674, or circle Reader Service 7.

ANIMATION RECORDER

The Matrox Animation Express (MAX) system from Matrox allows 3-D anima-

tions to be played back directly from hard disk in real time.

The system also eliminates frame-by-frame recording, as well as mechanical glitches, skipped frames and tape dropouts.

Full CCIR-601 video is supported in NTSC or PAL, while real-time capture to disk simplifies rotoscoping.

For further information, contact the company in Canada at telephone: +1-514-685-2630; FAX: +1-514-685-2853, or circle Reader Service 16.

DAT RECORDER

Sony's PCM-7030 and 7050 DAT recorders now feature Ver. 5 software designed to enhance the units' audio-for-video abilities.

Upgrades include comprehensive system set-ups for use in conjunction with Sony's BVE series of video editors.

In addition, the units can now issue a machine ID via their nine-pine interfaces to aid interfacing with other devices.

Error rate output is available through RS-422 interfaces.

For further information, contact the company in Europe at telephone: +44-1256-483646; FAX: +44-1256-812232, or circle Reader Service 54.

STANDARDS CONVERTER

The Cyrus Prime standards converter from AVS Broadcast features four-field, four-line linear conversion and an upgradeable motion compensation processor.

All inputs and outputs are 10-bit and interfaces are available to all main I/O formats.

The system also features bi-directional conversion between PAL, NTSC, NTSC 4.43 and SECAM.

For further information, contact the company in the U.K. at telephone: +44-81-391-5678; FAX: +44-81-391-5409, or circle Reader Service 126.

CONVERTER LENSES

Fujinon has introduced switchable "Ratio Converter" lenses for 16:9/4:3 operation.

Fitted inside select 2/3-inch hand-held lenses, the Ratio Converter compensates for the comparative loss in field angle performance when a camera is switched from widescreen to normal aspect ratio.

The unit also compensates in both 1x and 2x extender positions.

For further information, contact Fujinon in Japan at telephone: +81-48-668-2152; FAX: +81-48-651-8517, or circle Reader Service 123.

SPECIAL REPORT

Animators Captured by Motion

by Daniel Rappaport

Motion capture is quickly becoming one of the hottest things to hit the graphics and animation industry since morphing. An increasing number of high-profile film- and video-based 3-D computer animation projects have received attention for incorporating motion capture technology. And some in the animation community contend that these projects would have been impossible without motion capture techniques.

To some animation observers, motion capture is a stunning development in an indus-

try known for being on the technical edge. Others, however, view motion capture as a new, highly problematic and very controversial technique for 3-D computer animation. To them, motion capture introduces more problems than it solves.

In essence, depending on who you talk to, motion capture will either solve all your problems or spawn swarms of new, unforeseen and previously un-encountered new problems.

As it is most commonly conceived, motion capture consists of the following: the bodies of "actors" performing desired behavior sampled at repeated intervals. A variable

number of points on the actors' bodies may be of interest, and the resulting data sets of these points are recorded as digital data. These data sets can then be applied as motion to 3-D models via custom or off-the-shelf animation packages. Often, varying degrees of post processing or editing of the data may be necessary as well.

DISNEY IN MOTION

Is the concept of motion capture all that recent? Actually, no. It is not well known, but Disney experimented with such techniques years ago, albeit for possible use in

their theme parks with robotic figures such as Abraham Lincoln or Mark Twain. It was thought that it would be much easier to exhibit life-like (translation: human-like) motion in theme-park robots if the motion were actually copied from real humans.

Also, do not forget that there have been other cases of creating motion for mechanical forms (chiefly for non-human forms in movies). This might involve one or more people simultaneously manipulating hand-operated controls for real-time, on-camera performances (e.g., joysticks). Such tried-and-true methods often include puppeteering, but are not confined to applications made famous by the Muppets. Puppeteering techniques are now being used with computer animation, which could be construed as a form of motion capture.

Which brings to mind the question, exactly what is meant by "motion capture?" To the minds of many, motion capture consists solely of sampling human body motion in toto in order to imbue human-like animated forms with human-like motion. However, with current technology it is difficult to capture the entire range of human motion simultaneously.

For example, you might be interested in capturing kicking and punching motions to animate a karate character. The mechanisms suitable for capturing kicking and punching motions may not be suited for capturing facial expression; consequently, such a karate character application might utilize a variety of technologies in recorded multiple "takes."

While some animators shun the term motion capture, it has become such a buzz phrase it may be difficult to achieve widespread and universal agreement on the terminology. Others term the collection of previously discussed techniques by other names (performance animation or physically-based motion sampling).

INDUSTRIAL USE

A lot of attention has been given to the growing ranks of film- and video-based animation projects that have employed motion capture. However, there are many industries other than "traditional" film- and video-based 3-D computer animation that are also potentially well-suited to motion capture and thus are driving motion capture technology. These applications include virtual reality (VR), biomedical applications, networked games, military simulations, video games and CD-ROMs.

Why are these industries so interested in motion capture and why does the interest from CD-ROM game developers exceed, perhaps, the interest of film and video producers?

Part of the interest from many CD-ROM developers can be attributed to the branching nature of their plots or stories. At least in traditional film and video, production is confined to what appears on screen. However, CD-ROM games often employ numerous decision points throughout a game's progress, with different actions chosen by the user resulting in the presentation of different scenes. Consequently, a 15-minute CD-ROM experience may require much more animation than a 15-minute video because that 15-minute experience may only represent a few threads of a complex story line.

Given all these claims due motion capture, the buzz is not surprising. But does it really deliver? At this point, it is hard to say, as there has been less awareness of the pros and cons of motion capture. ■

Daniel Rappaport is a free-lance animator, programmer, producer and writer specializing in virtual reality, multimedia, visualization and human/machine interaction.

- Solid State (1 - 500 W).
- Compact and Reduced Design (19" Rack Format).
- Micro-Processor Controlled Parameters, visualized on LCD Screen, and possibility to telecommand via Modem and RS-232.
- Extensive use of Circuits for Protection (Adaptive Polarization, Lightning, Thermal, etc).
- SMT Mounting.
- Outstanding Price/Performance.

Introducing the most innovative family of TV transmitters and transposers on the market.

MIER COMUNICACIONES applies the know-how and technology, developed in advanced space programmes in designing and manufacturing the new family of LPTV Transmitters and Transposers.

More than 2.700 units in uninterrupted operation, as part of the most important TV Networks, guarantee the reliability of our equipment.

MMDS Goes Over the Horizon

Wireless Cable Tests in Kuwait and Bahrain Are Conducted Using Single-Cell Configuration

by James K. Vines

WIRELESS CABLE

Editor's note: Wireless cable, also known as multichannel multipoint distribution services (MMDS), is rapidly gaining stature as the method of choice for providing broadband video services to large populations. Not only is it inexpensive to build and maintain, but it has proven itself to be fairly rugged in areas of the world beset by transmission impairments.

To address this growing trend, TV Technology welcomes James K. Vines as a quarterly columnist. As a designer of wireless cable systems primarily in Northern Africa, Vines continuously tracks the latest developments and technological breakthroughs.

We hope his insights will prove valuable to our readers interested in finding new ways to bring television to the public.

Over-the-horizon (OTH) delivery of wireless cable (MMDS) service is currently the sweeping trend in this new industry. Ordinary S-band 2.5-2.7 GHz MMDS uses translators to provide OTH service, but because S-band MMDS transmits in AM, multiple translation degrades video quality.

A new way to provide MMDS over-the-horizon is being tested in Kuwait and Bahrain. It operates in the Ku-band at 11.7-12.2 GHz. A full 500 MHz block of frequencies is transmitted in FM. Astroguide, a U.S. company based in LaSalle, Illinois, provided the components for both tests.

This new method can be single or multi-celled (see figures 1 and 2). Presently both tests are of single cell configuration. To carry the 500 MHz block to another cell, an 18 GHz repeater system would be used.

FAR AND WIDE

The terrain for the Kuwait and Bahrain test cells is virtually flat. The effective cellular service radii are 30 km. The signal — which is encoded — is radiated in horizontal and vertical polarization, with 28 channels (14H, 14V) planned.

Home receiving systems consist

of a small Ku dish and 11.7-12.2 GHz LNB, mounting hardware, cable, and a receiver/decoder. Cost of the receiving system is about US\$270.

In a centralized system, all programming would originate from one cell — whether off-satellite, taped or locally produced — and the programming could be carried to other cells. The cells could overlap or be widely separated, and the service could thus be shaped to correspond to the distribution of the population. If the repeater system were configured for two-way service, programming could originate from any cell for instant distribution to any or all others.

How feasible would such a Ku-band system be elsewhere? Cost is modest enough: about US\$140,000 for a Ku cell headend including encoder, transmitter, enclosure and tower. With up to 32 PAL or SECAM channels, that is only US\$5,000 per channel. Need a second cell? Add about US\$80,000 per each 18 GHz repeater package, including tower and enclosure.

This is, in fact, less expensive than the older S-band technology. In Nigeria, where several S-band MMDS systems are operating, typically with six to eight channels, the cost of transmitters and transmitting antennas alone runs from \$35,000 to over \$150,000. Operators of these 6 and 8 channel systems have limited programming options for generating revenues.

As for climate considerations, the Kuwait and Bahrain test cells are adjacent to the Persian Gulf, where humidity is often high. Yet there are no problems with reception. In tropical rain

forest climates, such as coastal West Africa, Southeast Asia and equatorial South America, there are annual rainy seasons that introduce a certain amount of interference. To compensate for rain fade, the 18 GHz repeater systems need to be built with either a greater number of shorter hops or with larger transmit and receive antennas. Also, the Ku cells' effective radii would be reduced for parts of each day during the rainy season.

LEAFY CONCERNS

Terrain, particularly the amount of foliage, is also a consideration. Terrain is seldom ideal, but in most cases it can be dealt with using the Ku/Ka configuration. In most large cities, Ku receive dishes can be placed just above

other staple crops.

Ku service should perform well wherever the terrain is reasonably flat. This could include the coastal regions of Ecuador, Indonesia, India and the Philippines. Although much of these countries' terrains consist of dense jungles or mountains, the majority of their populations live along the coast.

For village and rural distribution, Ku service could be done in a single polarization, all free and largely advertiser-supported. Final delivery would be UHF with amplitude modulation. Anyone with a TV set and little more than a coat-hanger could receive the signal.

What about generating terrestrial interference that blocks reception of Ku satellite programming? Since Ku TVRO dishes throughout most of the Third World are relatively large, they tend to be located close to the ground. Thus, they are protected from terrestrial Ku transmission. Filtering would seldom be necessary.

The key to this type of service is the bandwidth. In the Ku range, bandwidth usage of a whopping 500 MHz amounts to just a fraction of the 12 GHz center frequency. Having so much bandwidth will allow Third World wireless entrepreneurs to

down, with corresponding increases in performance.

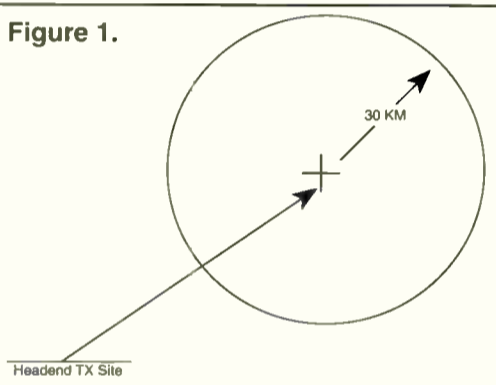

And by transmitting in both the horizontal and vertical polarization, it is possible to offer 32 channels of PAL or SECAM programming with FM modulation. In fact, it is possible to transmit across the entire 10.95-11.75 GHz spectrum. With 1,800 MHz to play with, 115 channels of PAL or SECAM would be easy.

This, of course, brings us to another dilemma: where to find the programming. I believe one of the best ways to take advantage of these new channel capacities is to foster educational television.

Since the encoding can be tiered, there can be a mix of free or reduced-cost channels, and this is where six of seven channels of ed-TV would fit. Some or all of these channels' revenues would come from advertisements, but that would depend on whether the programming is provided on reduced-fee or free channels.

To really make wireless systems a success, a vigorously growing local or regional "host" economy is needed. It is essential that wireless cable operators develop a business strategy that has local economic stimulation as a key objective. Wireless cable entrepreneurs would do well to think of their "business" as an industry. Industries are infrastructural, and infrastructure improvements (beyond the usual roads and dams) are high on the list of almost all developing countries.

Figure 1.

roof level for line-of-site reception. In rural areas and small villages where there are more trees, prospective receive sites probably will have to be tested.

In densely populated southern Nigeria, little of the original tropical rain forest remains. It has been largely replaced by a mix of palm agriculture and timber and rubber plantations. Compared to the original "high jungle" growth of up to 40 meters, much of today's commercial growth is 15 meters. There are also numerous open areas being cultivated with cassava, maize, yam and

On the Road with an EIC

The Mobile Engineer in Charge of Productions Needs A Basic Knowledge of the Television System

He is treated with careful deference. He is adept with mysterious tools and devices of unclear function. The depth and breadth of his knowledge of arcane subjects is unsurpassed. He is aloof and almost regal as he moves about the compound. He is calm and in possession of his faculties even when all those around him have abandoned theirs. But if you ask him a question at the wrong time he can be grumpy and abrupt. Who is this shaman, this modern-day Merlin? Why, he's the

Engineer-in-Charge, of course!

He is present at all large mobile shoots. With the truck driver, he arrives first and leaves last. You can find him working through the lunch hour to get the director another monitor with burned-in time code. You can find him on the phone with a software engineer halfway across the country to resolve a problem with the DVE. You can find him showing a camera operator how to set the back focus of his lens. You can find him repairing broken headsets and mic cables. He is responsible

for a wide range of functions.

Technically, he is responsible for keeping the whole show together. What are the duties of an EIC, and what type of person must he be in order to be effective at his job?

First and foremost, an EIC for mobile television productions has the responsibility to see that all technical operations run smoothly. To do this, he must have a solid understanding of all aspects of a television system: video, audio, data, communications, transmission, power. In addition to possessing the basic knowledge, he must be able to apply it in all sorts of difficult situations.

Specifically, he needs to be able to repair or bypass at a moment's notice any piece of equipment in his truck. If a DVE reboots itself five minutes before the show, he needs to know how to reset it. If a camera or its cable fails during the show, he must be able to rapidly identify the location of the problem and repair or replace the perpetrator. On a system level, if there are any problems with the truck or its connections, he must be able to track down the cause and fix it with an absolute minimum of disruption to the show.

A very important requirement of a

by Jon Hazell

MOBILE TELEVISION

can never lose his. He must be able to listen through the anger to negotiate a satisfactory solution to the problem, if possible. He must also be able to tactfully say "no" when it is appropriate.

Life on the road is never easy, and it contributes to the stress experienced by a mobile truck EIC. Interminable hours, sleeping in hotels, eating restaurant food, working away from family and home for long stretches of time, all require a flexible personality. Flexibility is one of the main requirements of a successful EIC.

A COMPLETE PACKAGE

Being the Engineer-In-Charge of a mobile production is a heavy responsibility, with job requirements that many television engineers would find completely

S Prepare yourself for Success

at NAB '95 ...

APRIL 9-13, 1995
LAS VEGAS
CONVENTION
CENTER
LAS VEGAS, NV

While it is clear that
an EIC needs to be a great engineer, that is
only half of the story.

competent EIC is to know where the quirks in a system are located. All technical systems develop personalities over time. Even a new piece of equipment has individual characteristics: a particular failure mode, a preference for operating in a certain temperature range, a tendency for settings to drift over time (or to remain unusually stable). When individual pieces of equipment are connected together in a system, individual characteristics add together into a discernable personality. A mobile truck, which spends a good deal of the time bouncing up and down the highway, enduring radical changes in temperature and humidity, and which is used by a different crew for each show, tends to have more personality than most other television systems.

WARMING UP

The EIC needs to know the tendencies of the equipment in his truck. A certain character generator may not boot up correctly until it has warmed up for at least an hour. A switcher may occasionally die and need to be reset following a certain procedure. When a mysterious personality disorder occurs in the truck, the EIC needs to recognize it and give it the appropriate counseling.

While it is clear that an EIC needs to be a great engineer, that is only half of the story. He is also usually the truck company's representative on site. He needs to be adept at communicating with his customer's representative, the producer and the crew.

Difficult situations can arise on the road and occasionally tempers are lost. The EIC

unattractive. The wide range of skills and personality traits needed to be a success is hard to find in one person, but for those with the ability and desire, there is no other job like it.

There can be tremendous personal satisfaction in using such a complex facility as a mobile truck to make high-quality television programs. You use your skills to adapt to the different situations you find at each site. You meet every challenge only to then pack it all up and drive away to another show in another location. There's always another challenge to meet tomorrow.

However, there is a special quiet time for the EIC in every successful mobile shoot. It happens after the show gets going and all the miscellaneous problems have been ironed out and before the end of the show when the hectic activity of the strike takes over everything.

It usually comes during the middle innings of baseball or the third quarter of a basketball game. It is a time to take stock. Everyone else is concentrating on the show. The equipment and the crew have fallen into a rhythm and everything is humming purposefully. It is a time when the EIC can stand back and feel the immense satisfaction of pulling it all together one more time. There's no feeling like it. ■

Jon Hazell is a staff engineer at MIRA/The Edit Suite, based in Portland, Oregon. The company handles a broad range of mobile production shoots and also maintains a production facility. Hazell may be reached c/o TV Technology.

EQUIPMENT EXCHANGE

TV Technology's Equipment Exchange provides a FREE listing service for all broadcast and pro-video end users. Brokers, dealers, manufacturers and other organizations who sell used equipment on an occasional basis can participate in the Equipment Exchange on a PAID basis. SCENARIA – THE FIRST CHOICE FOR AUDIO POST-PRODUCTION

Ed Golya and Danny McClelland, Avenue Edit

Avenue Edit is one of the most successful post-production companies in Chicago. It has built its reputation by providing the highest quality of creative and technical service to its prestigious client base.

Clients include:
Ogilvy and Mather,
Leo Burnett Company,
Foote, Cone & Belding,
DDB Needham,
J Walter Thompson and
Tatham Euro RSCG.

AVENUE EDIT, CHICAGO
"We believe Scenaria is the best tool available for audio post. Our clients are always amazed by Scenaria's power and integration; all functions and project information reside in one system, making revisions quick and painless. And SoundNet networking lets us share resources between our two Scenaria systems."

Rick Wilson, The Post Group

THE POST GROUP, HOLLYWOOD

"The ergonomics of Scenaria attracted us to the system. We needed an automated system, but were limited in the amount of space available for its installation. Scenaria has solved both problems allowing recording, editing and mixing to be carried out on a compact, uncluttered work surface, and in the digital domain."

The Post Group is a full service post-production facility with a four room audio department. Their ScreenSound and Scenaria systems are used for a variety of projects from music videos and commercials to interactive video games.

Projects include:
Paul McCartney
World Tour video.
Music videos for
artists such as Prince,
Hammer, Ice Cube and
Trans-Siberian
Orchestra.
