INTRODUCTION

Though I've kept engineering notebooks for 15 years, the idea for this notebook came from Gary Burkhart, Radio Shack's parts buyer, and Dave Gunzel, manager of Radio Shack's publications division. Gary has long wanted to include in his parts line a no-frills sourcebook of circuits for every Radio Shack IC. He and Dave have invested many hours answering my questions, providing components and technical information and reviewing the circuits. I'm grateful for their assistance.

Unless otherwise acknowledged, the circuits in this notebook are adapted from these sources:

1. Applications information published by the manufacturers of the various ICs.
2. My engineering notebooks.
3. "Experimenter's Corner" and "Project of the Month," two columns I write each month for POPULAR ELECTRONICS magazine.

Many of the circuits were developed specifically for this notebook. I hope you enjoy working with them as much as I have!

Forest M. Mims, III

HOW TO USE THIS BOOK

To squeeze the maximum number of circuits into this notebook, only essential information is provided. Therefore you will want to use this notebook in conjunction with Radio Shack's "Semiconductor Reference Handbook" and other data books.

For a quickie review of important components and construction tips, read the next few pages. The remainder of the notebook is divided into two major sections: digital and linear. The digital section is further divided into two major IC families: MOS/CMOS and TTL/LS. The chips in each section are organized according to function, not numerical sequence.

Though most circuits in this book can function on their own,

consider them as building blocks you can connect to other circuits to accomplish new applications. Experiment! Change resistors and capacitors in RC circuits to alter frequencies and timing. Add new functions. Above all, work with as many different chips as you can. If you've always used TTL, you'll be impressed with the operating flexibility of CMOS. If your forte is digital logic, you'll be amazed at what you can do with an op-amp. Finally, keep a record of your experiments and circuit designs. A notebook with a grid ruling like this one is best, but a 50¢ spiral notebook is OK.

For beginners only....Be sure to read the next few pages! Begin with simple chips (gate packages, timers, op-amps, etc.), and you'll soon be ready for more advanced circuits and projects. Good luck!

REVIEWING THE BASICS

INTRODUCTION

"Can I use a 0.22 uF capacitor instead of a 0.10 uF unit?"

"Is it OK to substitute a 12,000 ohm resistor for a 10,000 ohm unit?"

This section will tackle these common questions and many others. Master them, and you will be well prepared to tackle the circuits in this book!

RESISTORS

Resistors limit the flow of electrical current. A resistor has a resistance (R) of 1 ohm if a current (I) of 1 ampere flows through it when a potential difference (E) of 1 volt is placed across it. In other words:

$$R = \frac{E}{I} \text{ (or) } I = \frac{E}{R} \text{ (or) } E = IR$$

These handy formulas form Ohm's law. Memorize them! You'll use them often.

Resistors are identified by a color code:

COLOR	1	2	3 (Multiplier)
BLACK	0	0	1
BROWN	1	1	10
RED	2	2	100
ORANGE	3	3	1000
YELLOW	4	4	10,000
GREEN	5	5	100,000
BLUE	6	6	1,000,000
VIOLET	7	7	10,000,000
GRAY	8	8	100,000,000
WHITE	9	9	(none)

A fourth color band may be present. It specifies the tolerance of the resistor. Gold is $\pm 5\%$ and silver is $\pm 10\%$. No fourth band means $\pm 20\%$.

Since no resistor has a perfect tolerance, it's often OK to substitute resistors. For example, it's almost always OK to use a 1.8K resistor in place of a 2.0K unit. Just try to stay within 10-20% of the specified value.

What does K mean? It's short for 1,000. 20K means 20 x 1,000 or 20,000 ohms. M is short for meg-ohm or 1,000,000 ohms. Therefore a 2.2M resistor has a resistance of 2,200,000 ohms.

Resistors which resist lots of current must be able to dissipate the heat that's produced. Always use resistors with the specified power rating! No power rating specified? Then it's usually OK to use 1/4 or 1/2 watt units.

Almost every electronic circuit uses resistors. Here are three of the most important applications for resistors:

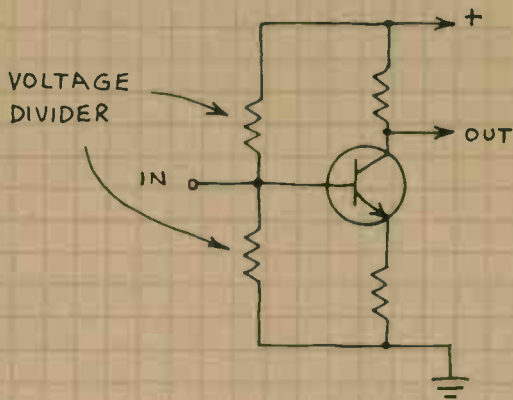

1. Limit current to LEDs, transistors, speakers, etc.
2. Voltage division. For instance:

The voltage at ? is $I \times R_2$. I means the current through R_1 and R_2 . So $I = 10 / (R_1 + R_2)$ or 0.005 amperes. Therefore, $? = (0.005) \times (1000)$ or 5 volts.

Note that the total resistance of R_1 and R_2 is simply $R_1 + R_2$. This rule provides a handy trick for making custom resistances.

Voltage dividers are used to bias transistors:

They're also a convenient source of variable voltage:

And they're useful in voltage sensing circuits. See the comparator circuits in this notebook.

3. They control the charging time of capacitors. Read on...

CAPACITORS

Capacitors store electrical energy and block the flow of direct current while passing alternating current. Capacitance is specified in farads. One farad represents a huge capacitance so most capacitors have values of small fractions of a farad:

1 microfarad (uF) = 10^{-6} farad
 1 picofarad (pF) = 10^{-12} farad
 or
 1 uF = 1,000,000 pF

The value of a capacitor is usually printed on the component. The uF and pF designations may not be present. Small ones marked 1-1000 are rated in pF; larger ones

marked .001-1000 are rated in uF.

Electrolytic capacitors provide high capacity in a small space. Their leads are polarized and must be connected into a circuit in the proper direction.

Capacitors have a voltage rating. It's usually printed under the capacity marking. The voltage rating must be higher than the highest expected voltage (usually the power supply voltage).

Caution: A capacitor can store a charge for a considerable time after power is removed. This charge can be dangerous! A large electrolytic capacitor charged to only 5 or 10 volts can melt the tip of a screwdriver placed across its leads! High voltage capacitors can store a lethal charge! Discharge a capacitor by carefully placing a resistor (1K or more; use Ohm's law) across its leads. Use only one hand to prevent touching both leads of the capacitor.

Important capacitor applications:

1. Remove power supply spikes. (Place 0.01-0.1 uF across power supply pins of digital ICs. Stops false triggering.)
2. Smooth rectified AC voltage into steady DC voltage. (Place 100-10,000 uF across rectifier output.)

3. Block DC signal while passing AC signal.

4. Bypass AC signal around a circuit or to ground.

5. Filter out unwanted portions of a fluctuating signal.

6. Use with resistor to integrate a fluctuating signal:

7. Or to differentiate a fluctuating signal:

8. Perform a timing function:

C will quickly charge...then slowly discharge through R.

9. Store a charge to keep a transistor turned off or on.

10. Store a charge to be dumped through a flashtube or LED in a fast and powerful pulse.

Can you substitute capacitors?

In most cases changing the value of a capacitor 10% or even 100% will not cause a malfunction, but circuit operation may be affected. In a timing circuit, for example, increasing the value of the timing capacitor will increase the timing period. Changing the capacitors in a filter will change the filter's frequency response. Be sure to use the proper voltage rating. And don't worry about the difference between 0.47 and 0.5 uF.

SEMICONDUCTORS

Usually made from silicon. Be sure to observe all operating restrictions. Brief descriptions of important semiconductor devices:

DIODES

Permit current to flow in but one direction (forward bias). Used to rectify AC, allow current to flow into a circuit but block its return, etc.

ZENER DIODES

The zener diode is a voltage regulator. In this typical circuit, voltage exceeding the diode's breakdown voltage is shunted to ground:

DI = 6 VOLT ZENER DIODE

Zeners can also protect voltage sensitive components and provide a convenient reference voltage.

LIGHT EMITTING DIODES

LEDs emit green, yellow, red or infrared when forward biased. A series resistor should be used to limit current to less than the maximum allowed:

$$R_s = \frac{V_{CC} - V_{LED}}{LED_I}$$

Example: V_{LED} of red LED is 1.7 volts. For a forward current (LED_I) of 20 mA at $V_{CC} = 5$ volts, $R = 330$ ohms. Don't exceed LED_I !!

Infrared LEDs are much more powerful than visible LEDs, but their radiation is totally invisible. Use them for object detectors and communicators.

TRANSISTORS

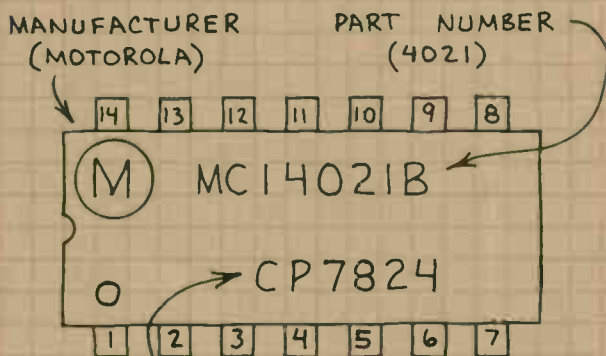

In this notebook, transistors are used as simple amplifiers and switches that turn on LEDs. Any general purpose switching transistors will work.

INTEGRATED CIRCUITS

Since an IC is a complete circuit on a silicon chip, you must observe all operating restrictions. Reversed polarity, excessive supply voltage and sourcing or sinking too much current can destroy an IC. Be sure to pay close attention to the location of the power supply pins! Most ICs are packaged in 8, 14 or 16 pin plastic DIPs (Dual In-line Packages). A notch or circle is near pin 1:

When the IC is right side up, pin 1 is at lower left:

DATE CODE:

78 = 1978
24 = 24th WEEK

Incidentally, a date code may not be present, but other numbers may be...and the date code is not always below the device number:

Store ICs in a plastic cabinet if you can afford one. Or insert them in rows in a styrofoam tray (the kind used for meat in a grocery store). CAUTION: Never store MOS/CMOS ICs in ordinary non-conductive plastic. See p. 12.

CIRCUIT BUILDING

Build your circuits on a solderless breadboard to make changes and find bugs. Then make permanent versions. Radio Shack plastic modular sockets (276-173, etc.) are ideal. They include two socket rows for power supply connections and snap rails for attaching sockets together. Parts and wires can be inserted directly into the holes in the socket.

For permanent circuits, use Radio Shack PC boards. Catalog numbers 276-024 and 276-151 are ideal for simple IC projects. Use larger universal PC boards for more complex projects (276-152 & 276-157). You can cut them into smaller sections with a nibbler tool or small saw.

I prefer to use wrapping wire for IC projects. Insert wrapping sockets in board and make connections with a Wire-Wrapping tool (such as 276-1570). Apply wrapping wire directly to leads of transistors, resistors, etc. and solder in place.

NOTES

DIGITAL INTEGRATED CIRCUITS

INTRODUCTION

DIGITAL ICs ARE 2-STATE DEVICES. ONE STATE IS NEAR 0 VOLTS OR GROUND (LOW OR L) AND THE OTHER IS NEAR THE IC'S SUPPLY VOLTAGE (HIGH OR H). SUBSTITUTE 0 FOR L AND 1 FOR H AND DIGITAL ICs CAN PROCESS INDIVIDUAL BINARY DIGITS (BITS) OR MULTIPLE BIT WORDS. A 4-BIT WORD IS A NIBBLE AND AN 8-BIT WORD IS A BYTE.

THE BINARY SYSTEM

IT'S VERY HELPFUL TO KNOW THE FIRST 16 BINARY NUMBERS. IF 0=L AND 1=H, THEY ARE:

- | | |
|-------------|--------------|
| 0 - L L L L | 8 - H L L L |
| 1 - L L L H | 9 - H L L H |
| 2 - L L H L | 10 - H L H L |
| 3 - L L H H | 11 - H L H H |
| 4 - L H L L | 12 - H H L L |
| 5 - L H L H | 13 - H H L H |
| 6 - L H H L | 14 - H H H L |
| 7 - L H H H | 15 - H H H H |

NOTE THAT L L L L (0) IS AS MUCH A NUMBER AS ANY OTHER NUMBER.

MOS/CMOS INTEGRATED CIRCUITS

INTRODUCTION

MOS ICs CAN CONTAIN MORE FUNCTIONS PER CHIP THAN TTL/LS AND ARE VERY EASY TO USE. MOST CHIPS IN THIS SECTION ARE CMOS (COMPLEMENTARY MOS). THEY CONSUME VERY LITTLE POWER AND OPERATE OVER A +3-15 VOLT RANGE. CMOS CAN BE POWERED BY THIS:

OR YOU CAN USE A LINE POWERED SUPPLY MADE FROM A 7805/7812/7815. SEE THE LINEAR SECTION.

INCIDENTALLY, YOU CAN POWER A CMOS CIRCUIT FROM TWO SERIES CONNECTED PENLIGHT CELLS, BUT A 9-12 VOLT SUPPLY WILL GIVE BETTER PERFORMANCE.

OPERATING REQUIREMENTS

1. THE INPUT VOLTAGE SHOULD NOT EXCEED V_{DD} ! (TWO EXCEPTIONS: THE 4049 AND 4050.)
2. AVOID, IF POSSIBLE, SLOWLY RISING AND FALLING INPUT SIGNALS SINCE THEY CAN CAUSE EXCESSIVE POWER CONSUMPTION. RISETIMES FASTER THAN 15 MICROSECONDS ARE BEST.
3. ALL UNUSED INPUTS MUST BE CONNECTED TO V_{DD} (+) OR V_{SS} (GND). OTHERWISE ERRATIC CHIP BEHAVIOR AND EXCESSIVE CURRENT CONSUMPTION WILL OCCUR.
4. NEVER CONNECT AN INPUT SIGNAL TO A CMOS CIRCUIT WHEN THE POWER IS OFF.
5. OBSERVE HANDLING PRECAUTIONS.

HANDLING PRECAUTIONS

A CMOS CHIP IS MADE FROM PMOS AND NMOS TRANSISTORS. MOS MEANS METAL-OXIDE-SILICON (OR SEMICONDUCTOR). P AND N REFER TO POSITIVE AND NEGATIVE CHANNEL MOS TRANSISTORS. AN NMOS TRANSISTOR LOOKS LIKE THIS:

A PMOS TRANSISTOR IS IDENTICAL EXCEPT THE P AND N REGIONS ARE EXCHANGED. THE SiO₂ (SILICON DIOXIDE) LAYER IS A GLASSY FILM THAT SEPARATES AND INSULATES THE METAL GATE FROM THE SILICON SUBSTRATE. THIS FILM IS WHY A MOS TRANSISTOR OR IC PLACES PRACTICALLY NO LOAD ON THE SOURCE OF AN INPUT SIGNAL. THE FILM IS VERY THIN AND IS THEREFORE EASILY PUNCTURED BY STATIC ELECTRICITY:

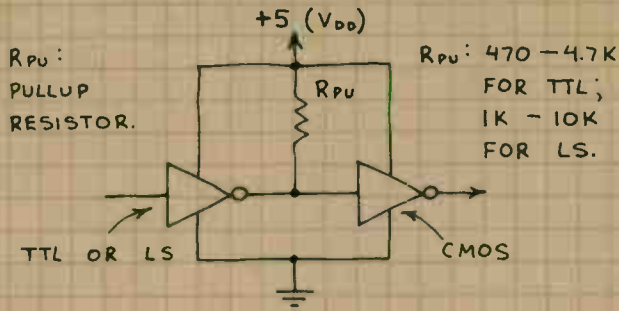

PREVENT STATIC DISCHARGE!

1. NEVER STORE MOS IC'S IN NONCONDUCTIVE PLASTIC "SNOW," TRAYS, BAGS OR FOAM.
2. PLACE MOS IC'S PINS DOWN ON AN ALUMINUM FOIL SHEET OR TRAY WHEN THEY ARE NOT IN A CIRCUIT OR STORED IN CONDUCTIVE FOAM.
3. USE A BATTERY POWERED IRON TO SOLDER MOS CHIPS. DO NOT USE AN AC POWERED IRON.

INTERFACING CMOS

1. IF SUPPLY VOLTAGES ARE EQUAL:

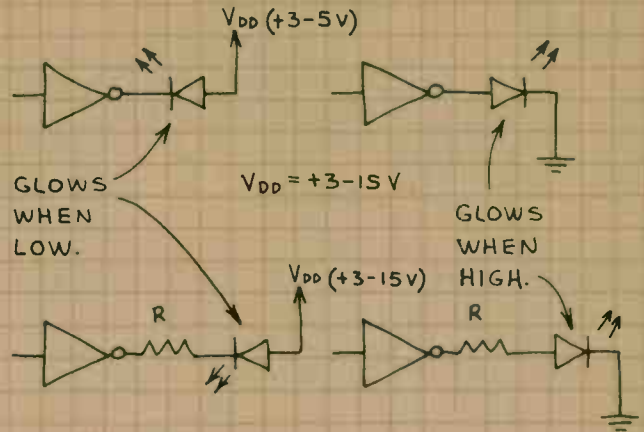

2. DIFFERENT SUPPLY VOLTAGES:

NOTE THAT CMOS MUST BE POWERED BY AT LEAST 5 VOLTS WHEN CMOS IS INTERFACED WITH TTL. OTHERWISE THE CMOS INPUT WILL EXCEED V_{DD} .

3. CMOS LED DRIVERS:

$$R = \frac{V_{DD} - 1.7}{.01} \quad (\text{FOR } 10 \text{ mA LED CURRENT})$$

USE 1000 OHMS FOR MOST APPLICATIONS.

CMOS LOGIC CLOCK

MANY CIRCUITS IN THIS SECTION REQUIRE A SOURCE OF PULSES. HERE'S A SIMPLE CMOS CLOCK:

TYPICAL VALUES: $R=100K$, $C=0.01-0.1\mu F$

OK TO USE 4049... BUT MUCH MORE CURRENT WILL BE REQUIRED.

CMOS TROUBLESHOOTING

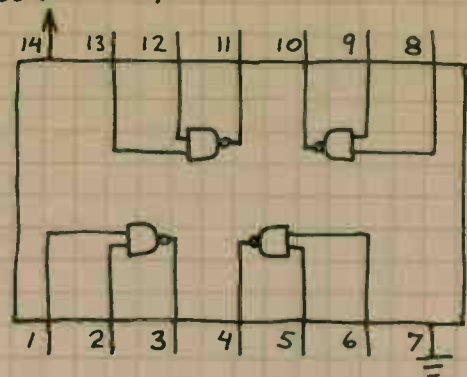

1. DO ALL INPUTS GO SOMEWHERE?
2. ARE ALL IC PINS INSERTED INTO THE BOARD OR SOCKET?
3. IS THE IC HOT? IF SO, SEE 1-2 ABOVE AND MAKE SURE THE OUTPUT IS NOT OVERLOADED.
4. DOES THE CIRCUIT OBEY ALL CMOS OPERATING REQUIREMENTS?
5. HAVE YOU FORGOTTEN A CONNECTION?

ADD THESE CONNECTIONS TO THE ADDRESSING CIRCUIT ON FACING PAGE.

SA-SJ: USE 8-POSITION DIP SWITCHES OR MINIATURE TOGGLES. OPEN=H; CLOSED=L

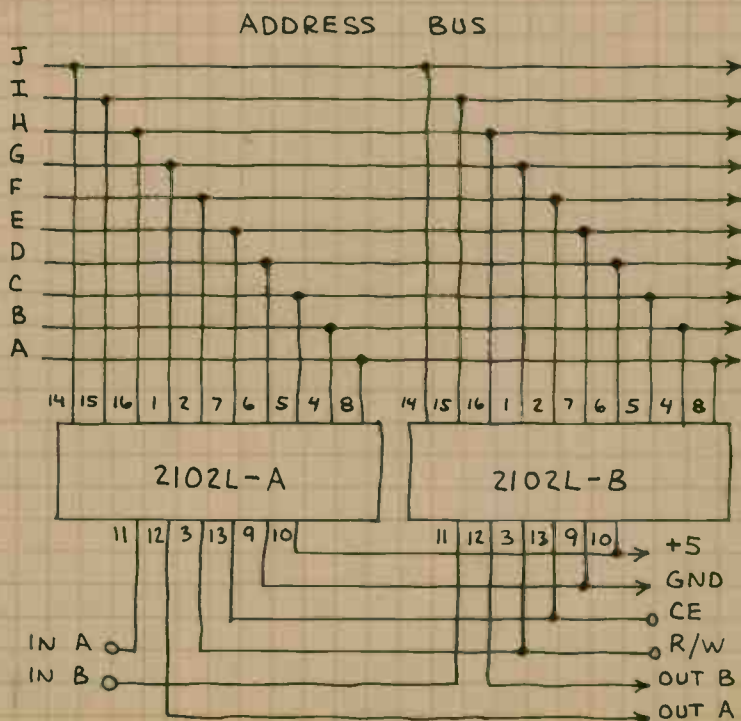

NORMALLY THE LOAD INPUT IS HIGH. MAKING LOAD LOW LOADS THE ADDRESS PROGRAMMED IN SWITCHES SA-SJ INTO THE 74193'S. THIS PERMITS A PROGRAMMED JUMP OR A MANUAL JUMP TO ANY ADDRESS.

SINGLE I/O PORT

ADD THIS CIRCUIT TO THE ADDRESSING CIRCUIT ON FACING PAGE. WHEN I/O (INPUT/OUTPUT) CONTROL IS H, PIN 3 OF THE 74LS367 ENTERS THIRD STATE (HI-Z) AND I/O PORT ACCEPTS INPUT DATA. WHEN PIN 3 OF THE 74LS367 IS L, I/O PORT OUTPUTS DATA. BOTH THESE OPERATIONS ARE DEPENDENT UPON THE STATUS OF THE 2102L CONTROL INPUTS.

DUAL ANALOG DELAY LINE SAD-1024A

CONTAINS TWO INDEPENDENT 512 STAGE SERIAL ANALOG DELAY (SAD) LINES (ALSO CALLED ANALOG SHIFT REGISTERS). OK TO USE EACH 512 STAGE SAD SEPARATELY OR IN SERIES. ANALOG DELAYS OF UP TO $\frac{1}{2}$ SECOND CAN BE ACHIEVED. A 2-PHASE CLOCK IS REQUIRED TO DRIVE INPUTS $\phi 1$ AND $\phi 2$. INPUT DATA RIDES THROUGH THE SAD ON ALTERNATING CLOCK PULSES AND APPEAR AT THE TWO OUTPUTS AFTER PASSING THROUGH ALL 512 STAGES. CONNECT V_{bb} TO V_{DD} (PIN 7) OR, FOR OPTIMUM RESULTS, TO 1 VOLT BELOW V_{DD} . THIS CHIP CAN BE TRICKY TO USE SINCE SEVERAL EXTERNAL ADJUSTMENTS ARE REQUIRED. CIRCUITS ON THIS PAGE EXPLAIN OPERATING REQUIREMENTS WHILE A COMPLETE CIRCUIT IS SHOWN ON FACING PAGE.

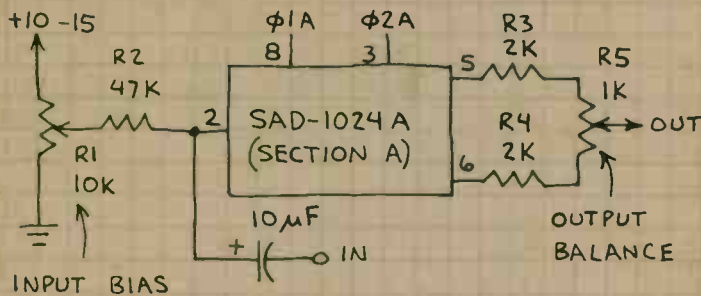

CAUTION: THIS NMOS CHIP IS VULNERABLE TO DAMAGE FROM STATIC DISCHARGE! FOLLOW CMOS HANDLING PROCEDURES.

SERIAL OPERATION

R1 CONTROLS BIAS TO SECTION B. NOTE THAT ONLY ONE OUTPUT OF A IS CONNECTED TO INPUT OF B.

DUAL ANALOG DELAY LINE (CONTINUED)

SAD-1024A

ADJUSTABLE FLANGER OR PHASER

ADJUST CIRCUIT FOR DESIRED EFFECT BY CONNECTING TRANSISTOR RADIO TO AUDIO INPUT. TUNE RADIO TO A TALK SHOW FOR BEST RESULTS. R13 AND R7 CONTROL BIAS TO SECTIONS A AND B OF THE SAD. R9 BALANCES THE SAD OUTPUTS. R2 CONTROLS THE CLOCK RATE. R17 IS THE MAIN BALANCE CONTROL. IT CONTROLS THE RELATIVE AMPLITUDES OF THE ORIGINAL AND DELAYED SIGNAL APPLIED TO THE MIXER. CONNECT THE OUTPUT TO A POWER AMPLIFIER. YOU MUST ADJUST BIAS CONTROLS PROPERLY FOR BEST RESULTS. SET R2 FOR LOW FREQUENCIES (3-8KHz) FOR SINGLE ECHO. USE HIGHER CLOCK FREQUENCIES (20-100 KHz) FOR HOLLOW, SWISHY SOUNDS. NOTE: THIS CIRCUIT IS NOT FOR BEGINNERS.

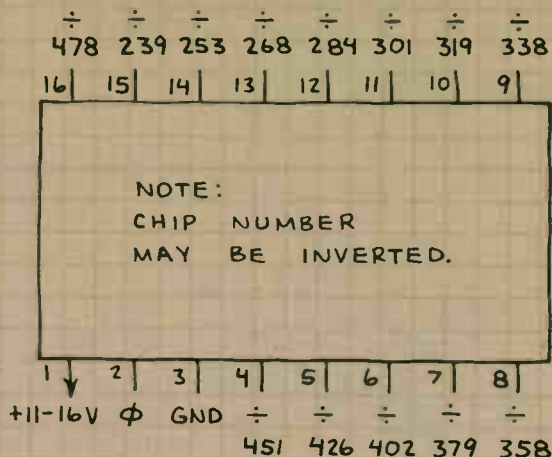

REVERBERATOR

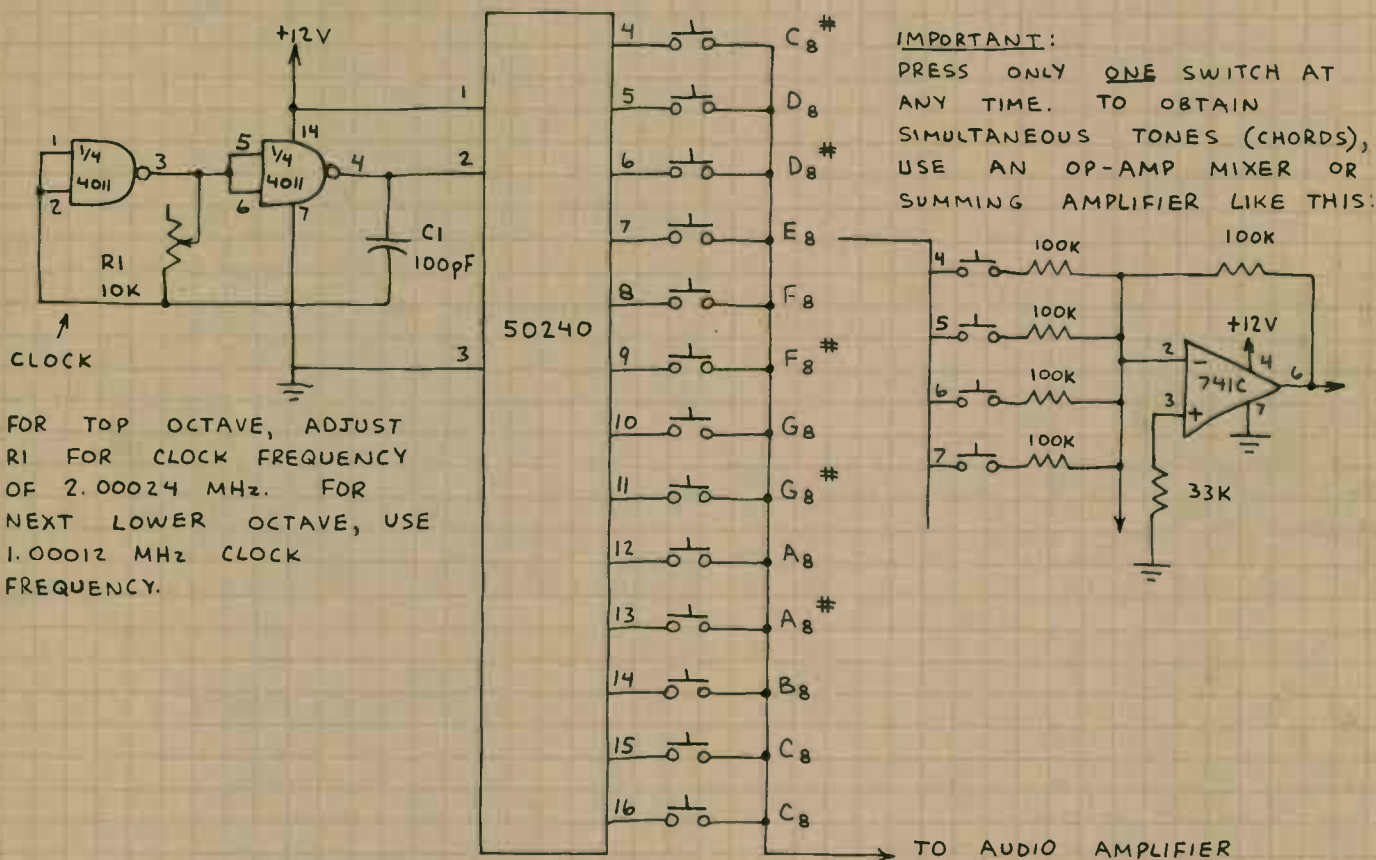

ADD THIS FEEDBACK CIRCUIT FOR UNUSUAL REVERBERATION EFFECTS. SLOW CLOCK FREQUENCIES GIVE MOST STRIKING REVERBERATIONS. TRY 5-20 KHz. FASTER CLOCK (20-100 KHz) AND CAREFUL ADJUSTMENT GIVES ROBOT-LIKE SOUND USED IN SOME SCIENCE FICTION MOVIES.

TOP OCTAVE SYNTHESIZER 550240

THIS PMOS CHIP ACCEPTS AN INPUT FREQUENCY (ϕ) AND THEN DIVIDES IT INTO A FULL OCTAVE PLUS ONE NOTE ON THE EQUALLY TEMPERED SCALE. THIS CHIP IS IDEAL FOR MUSIC SYNTHESIZERS, ORGANS, ETC. FOR TOP OCTAVE OPERATION, ϕ SHOULD BE 2.00024 MHz; LOWER FREQUENCIES GIVE LOWER OCTAVES.

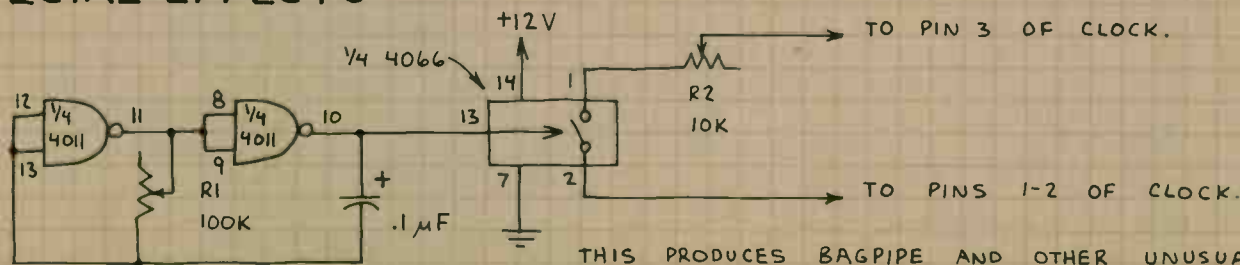

ADJUSTABLE OCTAVE SYNTHESIZER

FOR TOP OCTAVE, ADJUST R1 FOR CLOCK FREQUENCY OF 2.00024 MHz. FOR NEXT LOWER OCTAVE, USE 1.00012 MHz CLOCK FREQUENCY.

SPECIAL EFFECTS

THIS PRODUCES BAGPIPE AND OTHER UNUSUAL SOUNDS. ADJUST R1 TO VARY INTERRUPTION RATE.

NOTES

TTL/LS INTEGRATED CIRCUITS

INTRODUCTION

TTL IS THE BEST ESTABLISHED AND MOST DIVERSIFIED IC FAMILY. LS IS FUNCTIONALLY IDENTICAL TO TTL BUT IS SLIGHTLY FASTER AND USES 80% LESS POWER. TTL/LS CHIPS REQUIRE A REGULATED 4.75-5.25 VOLT POWER SUPPLY. HERE'S A SIMPLE BATTERY SUPPLY:

THE DIODE DROPS THE BATTERY VOLTAGE TO A SAFE LEVEL. BOTH CAPACITORS SHOULD BE INSTALLED ON THE TTL/LS CIRCUIT BOARD. CIRCUITS WITH LOTS OF TTL/LS CHIPS CAN USE LOTS OF CURRENT. USE A COMMERCIAL 5 VOLT LINE POWERED SUPPLY TO SAVE BATTERIES. OR MAKE YOUR OWN. (SEE THE 7805 ON PAGE 94.)

OPERATING REQUIREMENTS

1. V_{cc} MUST NOT EXCEED 5.25 VOLTS.
2. INPUT SIGNALS MUST NEVER EXCEED V_{cc} AND SHOULD NOT FALL BELOW GND.
3. UNCONNECTED TTL/LS INPUTS USUALLY ASSUME THE H STATE ... BUT DON'T COUNT ON IT! IF AN INPUT IS SUPPOSED TO BE FIXED AT H, CONNECT IT TO V_{cc} .
4. IF AN INPUT IS SUPPOSED TO BE FIXED AT L, CONNECT IT TO GND.
5. CONNECT UNUSED AND/NAND/OR INPUTS TO A USED INPUT OF THE SAME CHIP.
6. FORCE OUTPUTS OF UNUSED GATES H TO SAVE CURRENT (NAND—ONE INPUT H; NOR—ALL INPUTS L).

7. USE AT LEAST ONE DECOUPLING CAPACITOR (0.01-0.1 μ F) FOR EVERY 5-10 GATE PACKAGES, ONE FOR EVERY 2-5 COUNTERS AND REGISTERS AND ONE FOR EACH ONE-SHOT. DECOUPLING CAPACITORS NEUTRALIZE THE HEFTY POWER SUPPLY SPIKES THAT OCCUR WHEN A TTL/LS OUTPUT CHANGES STATES. THEY MUST HAVE SHORT LEADS AND BE CONNECTED FROM V_{cc} TO GND AS NEAR THE TTL/LS ICs AS POSSIBLE.

8. AVOID LONG WIRES WITHIN CIRCUITS

9. IF THE POWER SUPPLY IS NOT ON THE CIRCUIT BOARD, CONNECT A 1-10 μ F CAPACITOR ACROSS THE POWER LEADS WHERE THEY ARRIVE AT THE BOARD.

INTERFACING TTL/LS

1. 1 TTL OUTPUT WILL DRIVE UP TO 10 TTL OR 20 LS INPUTS.
2. 1 LS OUTPUT WILL DRIVE UP TO 5 TTL OR 10 LS INPUTS.
3. TTL/LS LED DRIVERS:

TTL/LS TROUBLESHOOTING

1. DO ALL INPUTS GO SOMEWHERE?
2. ARE ALL IC PINS INSERTED INTO THE BOARD OR SOCKET?
3. DOES THE CIRCUIT OBEY ALL TTL/LS OPERATING REQUIREMENTS?
4. HAVE YOU FORGOTTEN A CONNECTION?
5. HAVE YOU USED ENOUGH DECOUPLING CAPACITORS? ARE THEIR LEADS SHORT?
6. IS V_{cc} AT EACH CHIP WITHIN RANGE?

LINEAR INTEGRATED CIRCUITS

INTRODUCTION

THE OUTPUT OF A LINEAR IC IS PROPORTIONAL TO THE SIGNAL AT ITS INPUT. THE CLASSIC LINEAR IC IS THE OPERATIONAL AMPLIFIER. THIS GRAPH SHOWS THE LINEAR INPUT-OUTPUT RELATIONSHIP OF A TYPICAL OP-AMP CIRCUIT:

MANY NON-DIGITAL ICs—INCLUDING OP-AMPS—CAN BE USED IN BOTH LINEAR AND NON-LINEAR MODES. THEY ARE SOMETIMES DESCRIBED AS ANALOG ICs.

LINEAR ICs GENERALLY REQUIRE MORE EXTERNAL COMPONENTS THAN DIGITAL ICs. THIS INCREASES THEIR SUSCEPTABILITY TO EXTERNAL NOISE AND MAKES THEM A LITTLE TRICKIER TO USE. ON THE OTHER HAND, SOME LINEAR ICs CAN DO ESSENTIALLY THE SAME THING AS A NETWORK OF DIGITAL CHIPS.

HERE'S A BRIEF DESCRIPTION OF THE LINEAR CHIPS IN THIS SECTION:

VOLTAGE REGULATORS

PROVIDE A STEADY VOLTAGE, EITHER FIXED OR ADJUSTABLE, THAT IS UNAFFECTED BY CHANGES IN THE SUPPLY VOLTAGE AS LONG AS THE SUPPLY VOLTAGE IS ABOVE THE DESIRED OUTPUT VOLTAGE.

OPERATIONAL AMPLIFIERS

THE IDEAL AMPLIFIER... ALMOST. HIGH INPUT IMPEDANCE AND GAIN. LOW OUTPUT IMPEDANCE. GAIN IS

EASILY CONTROLLED WITH A SINGLE FEEDBACK RESISTOR. FET INPUT OP-AMPS (BIFETS) HAVE A VERY HIGH FREQUENCY RESPONSE. IT'S USUALLY OK TO SUBSTITUTE OP-AMPS IF BOTH ARE NORMALLY POWERED BY A DUAL POLARITY SUPPLY ($\frac{1}{2}$ LF353 FOR 741C, ETC)... BUT PERFORMANCE WILL IMPROVE OR DECREASE ACCORDING TO THE NEW OP-AMP'S SPECIFICATIONS.

COMPARATOR

SAME AS AN OP-AMP WITHOUT A FEEDBACK RESISTOR. ULTRA-HIGH GAIN GIVES A SNAP-LIKE RESPONSE TO AN INPUT VOLTAGE AT ONE INPUT THAT EXCEEDS A REFERENCE VOLTAGE AT THE SECOND INPUT.

TIMERS

USE ALONE OR WITH OTHER ICs FOR NUMEROUS TIMING AND PULSE GENERATION APPLICATIONS.

LED CHIPS

MOST IMPORTANT ARE A FLASHER CHIP AND A DOT-BARGRAPH ANALOG-TO-DIGITAL DISPLAY. VERY EASY TO USE.

OSCILLATORS

A VOLTAGE CONTROLLED OSCILLATOR AND A COMBINED VOLTAGE-TO-FREQUENCY AND FREQUENCY-TO-VOLTAGE CONVERTER. ALSO INCLUDED IS A TONE DECODER THAT CAN BE SET TO INDICATE A SPECIFIC FREQUENCY.

AUDIO AMPLIFIERS

THIS SECTION INCLUDES SEVERAL EASY TO USE POWER AMPLIFIERS THAT ARE IDEAL FOR DO-IT-YOURSELF STEREO, PUBLIC ADDRESS SYSTEMS, INTERCOMS AND OTHER AUDIO APPLICATIONS.

DOT/BAR DISPLAY DRIVER LM3914N

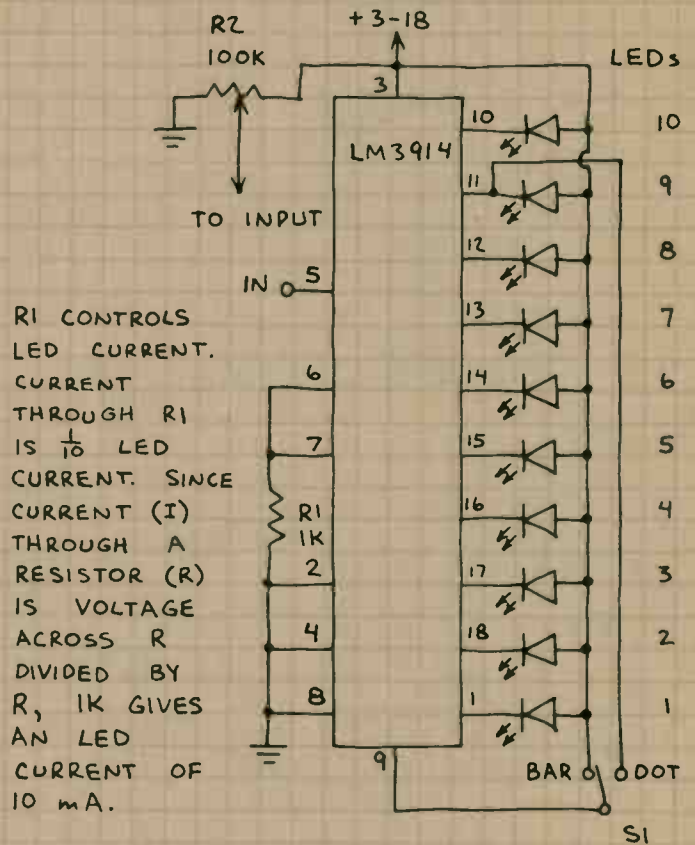

ONE OF THE MOST IMPORTANT CHIPS IN THIS NOTEBOOK. LIGHTS UP TO 10 LEDs (BAR MODE) OR 1-OF-10 LEDs (DOT MODE) IN RESPONSE TO AN INPUT VOLTAGE. CHIP CONTAINS A VOLTAGE DIVIDER AND 10 COMPARATORS THAT TURN ON IN SEQUENCE AS THE INPUT VOLTAGE RISES. HERE'S A SIMPLIFIED VERSION OF THE CIRCUIT:

R_{HI} AND R_{LO} ARE THE ENDS OF THE DIVIDER CHAIN. THE REFERENCE VOLTAGE OUTPUT (REF OUT) IS 1.2-1.3 VOLTS. CONNECT PIN 9 TO PIN 11 FOR DOT MODE OR +V FOR BAR MODE.

DOT/BAR DISPLAY

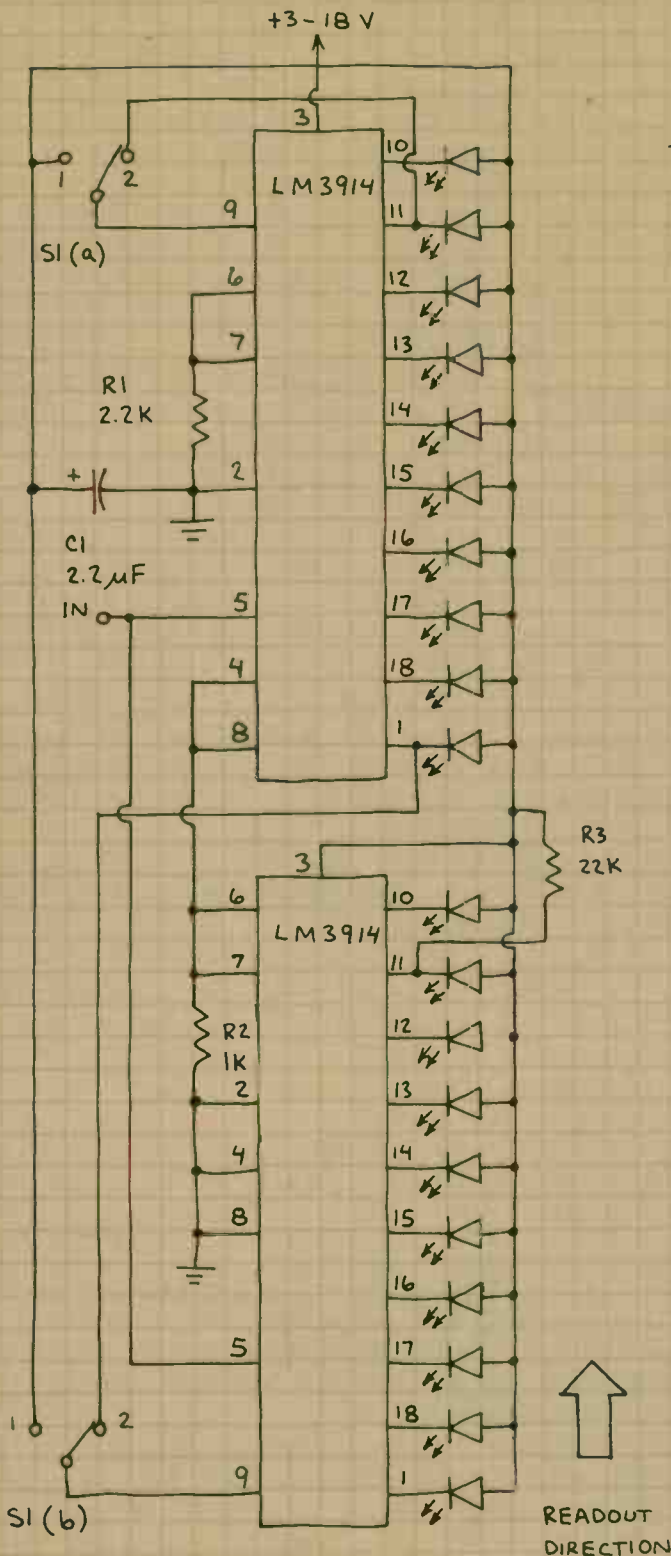

R_1 CONTROLS LED CURRENT. CURRENT THROUGH R_1 IS $\frac{1}{10}$ LED CURRENT. SINCE CURRENT (I) THROUGH A RESISTOR (R) IS VOLTAGE ACROSS R DIVIDED BY R , $1K$ GIVES AN LED CURRENT OF 10 mA.

WHEN +V = +3-18 VOLTS, THE READOUT RANGE IS 0.13-1.30 VOLTS. TO CHANGE RANGE TO 0.1-1.0 VOLT (0.1 VOLT PER LED), INSERT A $1K$ POTENTIOMETER BETWEEN PINS 6 AND 7. CONNECT VOLTMETER ACROSS PINS 5 AND 8 AND ADJUST R_2 FOR 1 VOLT AT PIN 5. THEN ADJUST $1K$ POT UNTIL LED 10 GLOWS. REPEAT THIS PROCEDURE FOR 0.1 VOLT AT PIN 5 AND LED 1. OK TO REPLACE THE $1K$ POT WITH A FIXED RESISTOR OF THE PROPER VALUE.

INTRODUCTION

This SEMICONDUCTOR REFERENCE HANDBOOK is intended to be just that—a reference handbook. It is not a definitive text book on semiconductors. It is a compilation of data on Radio Shack's line of prime-quality ARCHER semiconductors. Every ARCHER device covered in this Handbook is guaranteed prime—they are not "fall-outs" or "seconds"; all are top-quality, with known JEDEC, EIA or manufacturer's numbers.

At the back of the book is a cross-reference listing for replacement of Transistors, Diodes and other interchangeable semiconductor devices. The total number of cross-referenced devices exceeds 95,000. These cross-reference/replacement listings are computer-selected and are based on careful analysis of important parameters of the listed devices.

NOTE: If you can't find a replacement listing for a device you require, refer to the specification listings of the appropriate ARCHER family device. Often you will be able to make suitable replacements based on the information presented.

Each ARCHER replacement should meet or exceed the required parameters. However, due to differences in Quality Control and Manufacturing procedures (which often allow for or result in broad parameter variations), and because many of the ARCHER devices are capable of better performance than the original, Radio Shack does not guarantee, nor does it imply, that the listed items will provide an exact replacement in every instance. Therefore we recommend that you check the voltage and current requirements of the circuit (and other pertinent specifications) before replacement and compare with the specifications listed for that particular ARCHER device.

HOW TO USE THIS BOOK

This book has been prepared to aid in BOTH replacement and original applications of Semiconductor devices. The information included will be invaluable for the service technician as well as the circuit designer (whether he be an engineer, hobbyist, student or electronics experimenter).

We have included hints on handling Semiconductor devices, operating considerations, and some simple tests to aid you in evaluating the quality of the device in existing equipment (and thus the need for replacement). Also, a complete section on the specifications for each of the ARCHER devices is included: if there is any question in your mind about replacement equivalents or original use, refer to the appropriate category in the book. You will find the important characteristics specified there.

The next to last section is an extensive listing of replacement and cross reference between other manufacturer's numbers (both JEDEC/EIA 2N—numbers and in-house designations) and the ARCHER devices. This listing provides for the substitution of over 95,000 semiconductors with ARCHER devices.

The final section includes case style drawings and some handy reference notes, a comprehensive glossary of commonly used words, plus symbols and abbreviations. This section also includes some helpful indexes.

CARE AND HANDLING OF TRANSISTORS

Most modern transistors are somewhat immune from mechanical shock; however, it is always a good idea to keep them from excessive mechanical shocks, especially the metal-case type (avoid dropping, etc.).

When cutting transistor leads, use scissor-type cutting tools (rather than diagonal cutting tools which use a crimping action). Crimp-type cutting tools produce a mechanical shock along the lead which when transmitted to the semiconductor chip or material can cause fracture. Consider the force with which the cut lead flies off the crimp-type cutting tool and you have a good idea of the intensity of the equal and opposite force which acts on the lead going into the device.

It is always a good practice to use a heat-sink tool on a transistor lead when soldering (use a low-wattage iron—30-watts or less). Heat from soldering can cause problems (especially with certain types of semiconductor devices). Thus, to be sure, always use a heat-sink on the lead when soldering. Gripping the lead with long nose pliers between the solder connection and the case of the device makes a good heat-sink; or use a tool designed for such use.

SILICON OR GERMANIUM?

The quickest way to determine if a transistor is germanium or silicon type, is to check the normal emitter-base voltage drop. With NPN devices, if the base is approximately 0.25 volts positive with respect to the emitter, it is a germanium type. If the voltage is about 0.65 volts, it is a silicon type. For PNP devices, the voltage will be the same value, but opposite in polarity (0.25 volts for germanium and 0.65 for silicon).

OPERATING CONSIDERATIONS

Before replacing an original-equipment device with the recommended Archer Type:

(A) Compare the lead or terminal arrangement of the Archer replacement device with the lead or ter-

minimal arrangement of the original device. If these arrangements are different, and the original transistor is a "plug in" type, bend the leads of the ARCHER device so that the base, emitter and collector leads will mate with the original transistor leads. Trim the leads after soldering in place.

CAUTION: Be particularly careful about "pin-circle" and "in-line" lead break-out type transistors. Often one manufacturer makes a type with "in-line" leads, while another may make the same type with "pin-circle" configuration. **Doublecheck both the original and the replacement device before soldering or plugging in transistors.**

BOTTOM VIEW

(B) Certain considerations are involved whenever an original equipment transistor is replaced by one having a different type designation. When an ARCHER series transistor is used to replace an original equipment device in an untuned amplifier stage operating at a low signal level such as the untuned RF-amplifier (antenna) stage of a radio receiver, or a low-level AF amplifier stage, it is generally unnecessary to make any circuit adjustment to assure proper performance of the equipment. However, when a replacement is made in a tuned RF amplifier stage, it is always advisable to check the alignment of the associated tuned circuits to assure proper tracking and to achieve the required gain without loss of stability.

(C) When replacements are made in stages operating at relatively high power levels, such as Class A and Class B AF output stages of automobile radio receivers, phonographs and AF-amplifier systems, the transistor bias should be checked and adjusted, if necessary, to protect the ARCHER replacement transistors against excessive dissipation and to minimize distortion. Means for making adjustments are generally provided in the equipment, and the necessary instructions are usually given in the equipment manufacturer's service data.

(D) When installing an ARCHER transistor as a substitute for an original equipment type in an FM tuner, TV tuner, or other circuits operating at frequencies in the VHF or UHF regions, it is extremely important not to change any of the lead lengths or position of the original circuit. Before removing the original transistor, carefully note its position with respect to other circuit components as well as the lengths and placement of the transistor leads, and duplicate these details as closely as possible with the ARCHER replacement transistor. Failure to observe this precaution can result in improper tuning or circuit instability. The same holds true for any replacement of Integrated Circuits, specially in FM radios and TV Receivers. Failure to

observe this precaution can result in damage in the device. Transistor substitution in tuned circuits will often require realignment of the circuit.

SILICON VS SELENIUM RECTIFIERS

Silicon rectifiers are inherently more efficient than selenium or other metallic-oxide type rectifiers. When a silicon rectifier is used to replace a selenium rectifier in the power supply of a typical line-operated radio or TV receiver, the silicon rectifier will frequently deliver higher DC output voltage than the original device.

In some cases, this higher supply voltage may improve the performance of the equipment. However, in many other cases, it may immediately or eventually damage filter capacitors and/or other components which were designed to withstand only the voltage delivered by the original selenium rectifier. To prevent such damage, it is generally advisable to insert a power type resistor in series with the silicon rectifier either on the input side, between the AC supply and the rectifier, or on the output side between the rectifier and the first filter capacitor. The value of this resistor will depend on the required reduction in the DC output voltage and on the DC load current of the equipment. This value may be determined experimentally or calculated from the equation:

$$R = \frac{E}{I}$$

R is the required resistance in ohms.

E is the required reduction in DC output voltage in volts.

I is the DC load current in amperes.

The wattage rating of the resistor should be at least 2 X EI (in no case less than 10 watts).

SOLDERING PRECAUTIONS

Extreme care should always be used in making solder connections to semiconductors. Momentary application of excessive heat, or even prolonged application of a properly heated soldering tool to a semiconductor lead or terminal, can permanently damage the device. Observe the following precautions in soldering a semiconductor lead or terminal:

1. Solder as far as possible from the body of the semiconductor.

2. Never, apply heat or molten solder to a lead or terminal for longer than 10 seconds or at a point closer than 1/16 inch to the body of the device.

3. Use a low voltage iron (30 watts or less) specifically intended for use with transistors or miniature circuit components.

4. Keep the surfaces to be soldered clean and the tip of the soldering tool adequately tinned so that the connection can be made as quickly as possible.

5. Always use a heat sink on the lead when soldering. Gripping the lead or terminal with longnose pliers between the solder connection and case or body allows the pliers to act as a heat sink, conducting heat away from the internal elements of the device.

ABOUT CASE DIMENSIONS

In some instances, the case of an ARCHER semiconductor may be slightly taller or thicker than that of the original device or have a slightly different shape, particularly if the original device is a foreign type not made to U.S.A. EIA (JEDEC) standards. These mechanical differences should not affect the performance of the equipment in which the replacement is made and normally will not prevent or complicate the installation of the ARCHER replacement device.

You should realize that cross-reference substitution listings are created based **on electrical parameters (not necessarily on mechanical size or type)**. Thus, when you make substitutions based on our listings, check for physical/mechanical compatibility. If space is limited, it would be a good idea to check physical dimensions as well as electrical specs before making substitution.

GENERAL PRECAUTIONS

ARCHER transistor and ARCHER semiconductors should not be inserted or withdrawn from circuits with the power on, because transient currents may cause permanent damage to the device. In some cases ARCHER semiconductors are in metal cans and thus could possibly become shock hazards if they are allowed to operate at a voltage appreciably above or below ground potential.

For the most effective protection, a power transistor should be operated with an adequate heat sink and with the lowest value of resistance or impedance in the emitter-to-base circuit consistent with driving signal considerations. The transistor should be protected against extremely high collector voltage pulses which may be generated when the device is operated with inductive loads particularly when current transients are present.

When replacing a power transistor or rectifier which is attached to the equipment chassis, or to a special heat sink, observe the following precautions:

A. In the case of oxide coated metal washers or wafers, which are frequently used as electrical insulators between the cases of power transistors and the chassis or heat sink, it is important not to scratch, chip or otherwise damage the oxide surface.

B. When installing an ARCHER power transistor, where a mica or oxide coated metal washer was used to insulate the case of the original device electrically from the case, apply a thin coating of Heat Sink Compound (Radio Shack Number 276-1372) between the washer and the chassis or heat sink.

TESTING A TRANSISTOR

Before replacing a transistor, you want to be sure it needs to be replaced. Always check the entire circuitry to be sure the transistor requires replacement.

The best method for checking transistors is to use a good transistor checker (dynamic in-circuit and out-of-circuit type). However, a sensitive VOM can give you a good indication of the quality of the device.

I. In-Circuit Testing

- A. First, check to see if the emitter-base junction is forward-biased. An NPN transistor should show the base 0.2 to 0.65 volts positive with respect to the emitter (approximately 0.25 volts for a germanium type and 0.6 volts for silicon). A PNP transistor should show the base 0.2 to 0.65 volts negative with respect to the emitter (0.25 volts for germanium and 0.6 volts for silicon).
- B. Check to see if the device is functioning as an amplifier. Short the emitter-base junction to remove forward bias. Voltage at the collector lead should rise to approximately the potential of the collector supply buss line. Any difference is caused by ICES (collector-to-base leakage current). The closer the collector voltage approaches the buss line, the lower ICES is and the better the transistor.

II. Out-of-Circuit Testing

Again, for the best indication of transistor quality, use a good transistor checker. However, an ohmmeter can be used as described here.

Before using the ohmmeter, find out which polarity of the internal ohmmeter battery is connected to which test lead (not all ohmmeters have the + battery polarity connected to the red lead and the - battery polarity connected to the black lead). To determine the polarity of the leads when using the ohmmeter function, use an external voltmeter or study the schematic of your VOM.

Also, remember that in most transistor circuits you are dealing with low voltages and currents (in some cases, very low). Therefore, **NEVER** use RX1 scale (extensive currents can flow through a junction, permanently damaging the transistor). It is best to determine the maximum amount of current available in each resistance range before using an ohmmeter for testing semiconductor junctions.

After you have evaluated your VOM for the above and are sure you will not damage a transistor (with excessive current or voltage in any given ohmmeter range), proceed as follows:

- A. Small Signal PNP Germanium Transistors
 1. Connect the positive lead of your ohmmeter to the emitter. Connect the negative lead to the base. You should read 200-500 ohms.
 2. Connect the negative lead to the collector. You should read 10K-100K. Shorting collector base, the resistance should decrease.
- B. Small Signal NPN Germanium Transistors
Reverse the polarity of the leads; the readings should be approximately the same.
- C. Power PNP Germanium Transistors
 1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 35-50 ohms.
 2. Connect the negative lead to the collector. The reading should be several hundred ohms. Shorting collector to base, the resistance should decrease.

- D. Power NPN Germanium Transistors
Reverse the polarity of the leads; the reading should be approximately the same.
- E. Small Signal PNP Silicon Transistors
1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 1K-3K.
 2. Connect the negative lead to the collector. The reading should be very high (may show as an "open").
- F. Small Signal NPN Silicon Transistors
Reverse the polarity of the leads; the readings should be approximately the same.
- G. Power PNP Silicon Transistors
1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 200-1K.
 2. Connect the negative lead to the collector. The reading should be about 1 megohm or more.
- H. Power NPN Silicon Transistors
Reverse the polarity of the leads; the readings should be approximately the same.
- The resistance readings noted above can only be approximate; as long as you obtain somewhat proportionate readings (emitter-base readings as compared to emitter-collector), you can safely assume the transistor is OK.

HANDLING OF INTEGRATED CIRCUITS

Because MOS devices have extremely high input resistance, they are susceptible to damage when exposed to static electrical charges (even electrical charges that normally build up on the human body can cause damage). To avoid possible damage to the devices during handling, testing, or actual operation, the following procedures should be observed:

1. Except when being tested or in actual operation, the leads of devices should be in contact with a conductive material, to avoid build-up of static charge.
2. Soldering iron tips, tools, metal parts of fixtures and handling facilities should be grounded.
3. Transient voltages may cause permanent damage to the device if it is removed or inserted with the power on.
4. Do not apply signals to the input with the power supply off.
5. All unused input leads must be connected to either VSS or VDD (whichever is appropriate for the logic circuit involved).

GENERAL DESCRIPTION

ZNR varistors are zinc oxide resistors whose resistance changes as a function of the applied voltage. The ZNR has a bilateral and symmetrical V-I characteristic curve and can therefore be used in circuits in place of back-to-back zener diodes. This gives your circuit clamping protection in either direction. The ZNR provides a highly reliable and economical way to protect against repeated high voltage transients and surges such as those produced by lightning, switching surges and noise spikes.

FEATURES

- Excellent clamping voltage characteristic and fast response time (< 50 nsec.) when subjected to impulse surges. Eliminates the discharge lag that is indicative of gap-type arrestors.
- Bilateral and symmetrical V-I characteristic curve. The ZNR can, therefore, be used both in AC and in DC circuits, for protection of either positive or negative transients.

THYRISTORS

MU27

GENERAL DESCRIPTION

Thyristors and their trigger devices can take numerous forms, but they share these characteristics:

- They are "open circuits," capable of withstanding rated voltage until triggered.
- They become low-impedance current paths when triggered, and remain so, even after the trigger source is removed, until current through that path stops, or is reduced below a minimum "holding" level.

SCRs

Silicon-Controlled Rectifiers (SCRs) are Thyristors intended to switch load currents in one direction only, making them useful for DC and half-wave AC applications as well as full-wave applications, in which bidirectional current is routed in one direction through the SCR via a bridge rectifier.

TRIACs

Triacs are bidirectional Thyristors, in which a single trigger source turns the device on for load current in either direction. Because they do not require a bridge rectifier in order to handle full-wave AC, Triacs are useful in AC power applications that require full source power control capability to be applied to the load.

2.5×5cm SILICON SOLAR CELL

GENERAL DESCRIPTION

A solar cell is a silicon semiconductor device which converts light energy directly to electricity. A typical 2.5×5cm cell will produce 0.42 volt and up to .18 amp of usable current. The power generated is affected by the load resistance (circuit powered by cell) strength of sunlight and temperature.

Be extremely careful when soldering leads. Use only a very fine wire (#26 or thinner) and use a small soldering iron (less than 50 watts). Solar cells may be connected in series to produce more voltage and in parallel for more current.

DECADE COUNTER/DIVIDER

GENERAL DESCRIPTION

The 4017 is a five-stage Johnson decade counter with built-in code converter. High-speed operation and spike-free outputs are obtained by use of a Johnson decade counter design. This part can be used in frequency division applications as well as decade counter or decimal decode display applications.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$.

276-2449

GENERAL DESCRIPTION

The 4049 hex inverter/buffer is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These complementary MOS devices find primary use where low power dissipation and/or high noise immunity is desired. These devices provide logic-level conversion using only one supply voltage, V_{CC} . The input-signal high level (V_{IH}) can exceed the V_{CC} supply voltage for logic-level conversions. Two TTL/DTL loads can be driven when the devices are used as CMOS-to-TTL/DTL converters ($V_{CC} = 5.0\text{ V}$, $V_{OL} \leq 0.4\text{ V}$, $I_{OL} \geq 3.2\text{ mA}$). Note that pin 16 is not connected internally on this device; consequently connections to this terminal will not affect circuit operation.

INPUT/OUTPUT DESCRIPTION

Oscillator Input

The frequency of the internal oscillator is set by an RC network connected to the OSC input, as shown in Item 1. The R and C values for different frequencies is given in Item 2.

External Clock Input

If the internal oscillator is not used, the chip can be driven by an external clock applied to this input.

Clock Select Input

The internal oscillator or the external clock is selected by the proper logical level applied to this input. A logic "1" selects the external clock and logic "0" selects the internal oscillator. The clock select input has an internal pull up resistor.

Item 1 — LS7210 Oscillator Connection

Trigger Input

A positive or a negative transition at the trigger input initiates a delay in turning on or off the output. A negative transition always turns on the output with or without delay depending on the selected mode. A positive transition at the trigger input always turns off the output (with the exception of one-shot mode) with or without delay depending on the selected mode. The delay is a function of the oscillator frequency (or the external clock frequency) and the weighting factor programmed at the weighting factor inputs. The trigger input is clocked into the input latch with the negative edge of the external clock. All timings begin after the latch has been set up. The trigger input has an internal pull-up resistor.

Weighting Factor Input, LSB-MSB

A delay from the trigger input to the output is programmed by applying 1's complement binary weighted numbers at these 5 inputs. The exact equation for the delay is:

$$\text{Delay} = \frac{(1 + 1.023N)}{f} \text{ See Block Diagram Note 3}$$

Where f = The oscillator frequency and N = Weighting factor. All the weighting factor inputs have internal pull-up resistors.

**ITEM 5

LSB + 1	2
LSB + 2	4
LSB + 3	8
MSB	16

EXAMPLE: For a weighting factor of 25, inputs MSB, LSB + 3, and LSB should be programmed to logic "0".

Mode Select Inputs A&B

The chip can be programmed to operate in 4 different modes by applying the logic levels to inputs A&B as indicated in Item 3. The mode select inputs are clocked into the input latches with the negative edge of the external clock. These inputs should not be changed while a delay timing is in progress. The mode select inputs have internal pull-ups.

**ITEM 3
MODE SELECTION**

CONTROL		MODE
A	B	
1	1	Dual Delay
1	0	Delayed Release
0	1	Delayed Operate
0	0	One Shot

MODE DEFINITION: (See ITEM 4)

Dual Delay Mode

This is the Default Mode when the inputs A&B are left unprogrammed. The function of the Dual Delay mode is to provide a time delay on both the turn-on and turn-off of the output. Once turned on, the output will remain on as long as the trigger input is logic "0". Once turned off, the output will remain off as long as the trigger input is a logic "1".

Delayed Operate Mode

This mode causes a retriggerable delay in turning the output on in response to a negative edge at the trigger input. The output is turned off without delay in response to a positive transition at the trigger input.

Delayed Release Mode

This mode causes a retriggerable delay in turning off the output whenever there is a positive transition at the trigger input. The output is turned on without delay in response to a negative transition at the trigger input.

One-Shot Mode

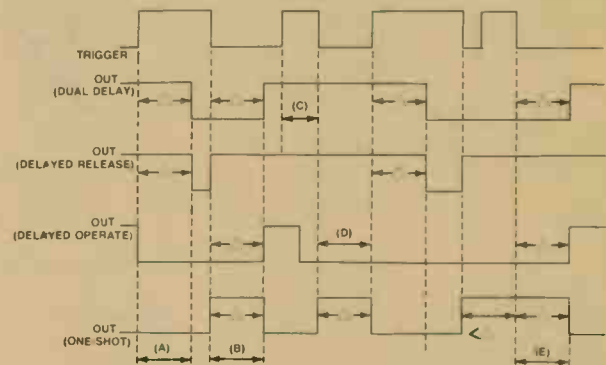

In this mode, the chip functions like a retriggerable monostable multi-vibrator. The output is turned on whenever there is a negative transition at the trigger input. At the end of the programmed delay, the output is turned off automatically. If there is a negative transition at the trigger input before the delay is over, the delay is restarted. A positive transition at the trigger input has no effect on the output in this mode.

Output

The output is an open drain FET. To obtain proper switching of the output between logic "0" and "1" levels, an external pull down resistor to V_{DD} must be used. If the output is used only as a current source, no such pull down is needed. The output is logically inverted with respect to the trigger input.

- Notes: 1. The blanking input (BI) must be open or held at a high logic level when output functions 0 thru 15 are desired. The ripple-blanking input (RBI) must be open or high, if blanking of a decimal zero is not desired.
2. When a low logic level is applied directly to the blanking input (BI), all segment outputs are H regardless of the level of any other input.
3. When ripple-blanking input (RBI) and inputs A, B, C, and D are at a low level with the lamp-test input high, all segment outputs go H and the ripple-blanking output (RBO) goes to a low level (response condition).
4. When the blanking input/ripple blanking output (BI/RBO) is open or held high and a low is applied to the lamp test input, all segment outputs are L.

† BI/RBO is wire-AND logic serving as blanking input (BI) and/or ripple-blanking output (RBO).

DIVIDE BY 2 OR 5, BCD COUNTER

GENERAL DESCRIPTION

This monolithic BCD counter contains four master-slave flip-flops and additional gating to provide a divide-by-two counter and a three-stage binary counter for which the count cycle length is divide-by-five.

This counter has a gated zero reset and gated set-to-nine inputs for use in BCD nine's complement applications.

To use maximum count length, the B input is connected to the Q_A output. The input count pulses are applied to input A and the outputs are as described in the appropriate truth table. A symmetrical divide-by-ten count can be obtained from the 90 counter by connecting the Q_D output to the A input and applying the input count to the B input which gives a divide-by-ten square wave at output Q_A.

APPLICATIONS INFORMATION

The Electronic Industries Association (EIA) RS232C specification details the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The 1488 quad driver and its companion circuit, the 1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the RS232C defined levels. The RS232C requirements as applied to drivers are discussed herein.

The required driver voltages are defined as between 5 and 15-volts in magnitude and are positive for a logic "0" and negative for a logic "1". These voltages are so defined when the drivers are terminated with a 3000 to 7000-ohm resistor. The 1488 meets this voltage requirement by converting a DTL/TTL logic level into RS232C levels with one stage of inversion.

The RS232C specification further requires that during transitions, the driver output slew rate must not exceed 30 volts per microsecond. The inherent slew rate of the 1488 is much too fast for this requirement. The current limited output of the device can be used to control this slew rate by connecting a capacitor to each drive output. The required capacitor can be easily determined by using the relationship $C = I_{OS} \times \Delta T / \Delta V$ from which Figure 1 is derived. Accordingly, a 330-pF capacitor on each output will guarantee a worst case slew rate of 30 volts per microsecond.

The interface driver is also required to withstand an accidental short to any other conductor in an interconnecting cable. The worst possible signal on any conductor would be another driver using a plus or minus 15-volt, 500-mA source. The 1488 is designed to indefinitely withstand such a short to all four outputs in a package as long as the power-supply voltages are greater than 9.0 volts (i.e., $V_{CC} \geq 9.0 V$; $V_{EE} \leq -9.0 V$). In some power-supply designs, a loss of system power causes a low impedance on the power-supply outputs. When this occurs, a low impedance to ground would exist at the power inputs to the 1488 effectively shorting the 300-ohm output resistors to ground. If all four outputs were then shorted to plus or minus 15 volts, the power dissipation in these resistors would be excessive. Therefore, if the system is designed to permit low impedances to ground at the power-supplies of the drivers, a diode should be placed in each power-supply lead to prevent overheating in this fault condition. These two diodes, as shown in Figure 2, could be used to decouple all the driver packages in a system. (These same diodes will allow the 1488 to withstand momentary shorts to the ± 25 -volt limits specified in the earlier Standard RS232B.) The addition of the diodes also permits the 1488 to withstand faults with power-supplies of less than the 9.0 volts stated above.

The maximum short-circuit current allowable under fault conditions is more than guaranteed by the previously mentioned 10 mA output current limiting.

OTHER APPLICATIONS

The 1488 is an extremely versatile line driver with a myriad of possible applications. Several features of the drivers enhance this versatility:

Output Current Limiting—this enables the circuit designer to define the output voltage levels independent of power-supplies and can be accomplished by diode clamping of the output pins. Figure 14 shows the 1488 used as a DTL to MOS translator where the high-level voltage output is clamped one diode above ground. The resistor divider shown is used to reduce the output voltage below the 300 mV above ground MOS input level limit.

Power-Supply Range—as can be seen from the schematic drawing of the drivers, the positive and negative driving elements of the device are essentially independent and do not require matching power-supplies. In fact, the positive supply can vary from a minimum seven volts (required for driving the negative pulldown section) to the maximum specified 15 volts. The negative supply can vary from approximately -2.5 volts to the minimum specified -15 volts. The 1488 will drive the output to within 2 volts of the positive or negative supplies as long as the current output limits are not exceeded. The combination of the current-limiting and supply-voltage features allow a wide combination of possible outputs within the same quad package. Thus if only a portion of the four drivers are used for driving RS232C lines, the remainder could be used for DTL to MOS or even DTL to DTL translation. Figure 15 shows one such combination.

APPLICATIONS INFORMATION

The Electronic Industries Association (EIA) has released the RS-232C specification detailing the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The 1488 quad driver and its companion circuit, the 1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the RS-232C defined levels. The RS-232C requirements as applied to receivers are discussed here. The required input impedance is defined as between 3000 ohms and 7000 ohms for input voltages between 3.0 and 25 volts in magnitude; and any voltage on the receiver input in an open circuit condition must be less than 2.0 volts in magnitude. The 1489 circuits meet these requirements with a maximum open circuit voltage of one V_{BE} .

The receiver shall detect a voltage between -3.0 and -25 volts as a logic "1" and input between $+3.0$ and $+25$ volts as a logic "0". On some interchange leads, an open circuit or power "OFF" condition (300 ohms or more to ground) shall be decoded as an "OFF" condition or logic "1". For this reason, the input hysteresis thresholds of the 1489 circuits are all above ground. Thus an open or grounded input will cause the same output as a negative of logic "1" input.

TLC555 TIMER
276-1718

GENERAL DESCRIPTION

The TLC555 is a monolithic timing circuit fabricated using the Lin CMOS™ process. Due to its high-impedance inputs (typically $10^{12}\Omega$), it is capable of producing accurate time delays and oscillations while using less expensive, smaller timing capacitors. The TLC555 achieves both monostable (using one resistor and one capacitor) and astable (using two resistors and one capacitor) operation. In addition, 50% duty cycle astable operation is possible using only a single resistor and one capacitor. The Lin CMOS™ process allows the TLC555 to operate at frequencies up to 2 MHz and be fully compatible with CMOS, TTL, and MOS logic. It also provides very low power consumption (typically 1 mW at $V_{DD} = 5V$) over a wide range of supply voltages ranging from 2 volts to 18 volts.

Threshold and trigger levels are normally two-thirds and one-third respectively of V_{DD} . These levels can be altered by use of the control voltage terminal. When the trigger input falls below trigger level, the flip-flop is set and the output goes high. If the trigger input is above the trigger level and the threshold input is above the threshold level, the flip-flop is reset and the output is low. The reset input can override all other inputs and can be used to initiate a new timing cycle. When the reset input goes low, the flip-flop is reset and the output goes low. Whenever the output is low, a low impedance path is provided between the discharge terminal and ground.

While the complementary CMOS OUTPUT is capable of sinking over 100 mA and sourcing over 10 mA, the TLC555 exhibits greatly reduced supply current spikes during output transitions.

FEATURES

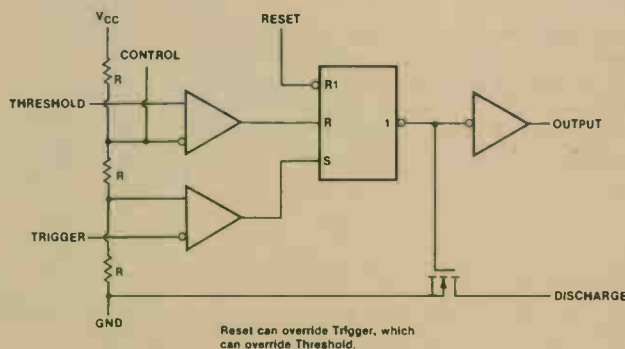

- Very low power consumption (1 mW typical at $V_{DD} = 5 V$)

- Complementary CMOS output capable of swinging rail to rail

QUAD OP AMP

GENERAL DESCRIPTION

The 324 series consists of four independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, dc gain blocks and all the conventional op amp circuits which now can be more easily implemented in single power supply systems. For example, the 324 series can be directly operated off of the standard +5 V_{DC} power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional +15 V_{DC} power supplies.

FEATURES

- Internally frequency compensated for unity gain
- Large dc voltage gain 100 dB
- Wide bandwidth (unity gain) 1 MHz (temperature compensated)
- Wide power supply range:
Single supply 3 V_{DC} to 30 V_{DC}
or dual supplies ±1.5 V_{DC} to ±15 V_{DC}
- Very low supply current drain (800 μA)—essentially independent of supply voltage (1 mW/op amp at +5 V_{DC})
- Low input biasing current 45 nA_{DC} (temperature compensated)
- Low input offset voltage 2 mV_{DC} and offset current 5 nA_{DC}
- Input common-mode voltage range includes ground
- Differential input voltage range equal to the power supply voltage
- Large output voltage swing 0 V_{DC} to V₊ - 1.5 V_{DC}

3-TERMINAL ADJUSTABLE POSITIVE REGULATOR

317T
276-1778

GENERAL DESCRIPTION

The 317T is an adjustable 3-terminal positive voltage regulator capable of supplying in excess of 1.5 A over a 1.2 V to 37 V output range. This device is exceptionally easy to use and requires only two external resistors to set the output voltage.

In addition to higher performance than fixed regulators, the 317T offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Normally, no capacitors are needed unless the device is situated far from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejection ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the 317T is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded.

It will also serve as a simple adjustable switching regulator, programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the 317T can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2 V where most loads draw little current.

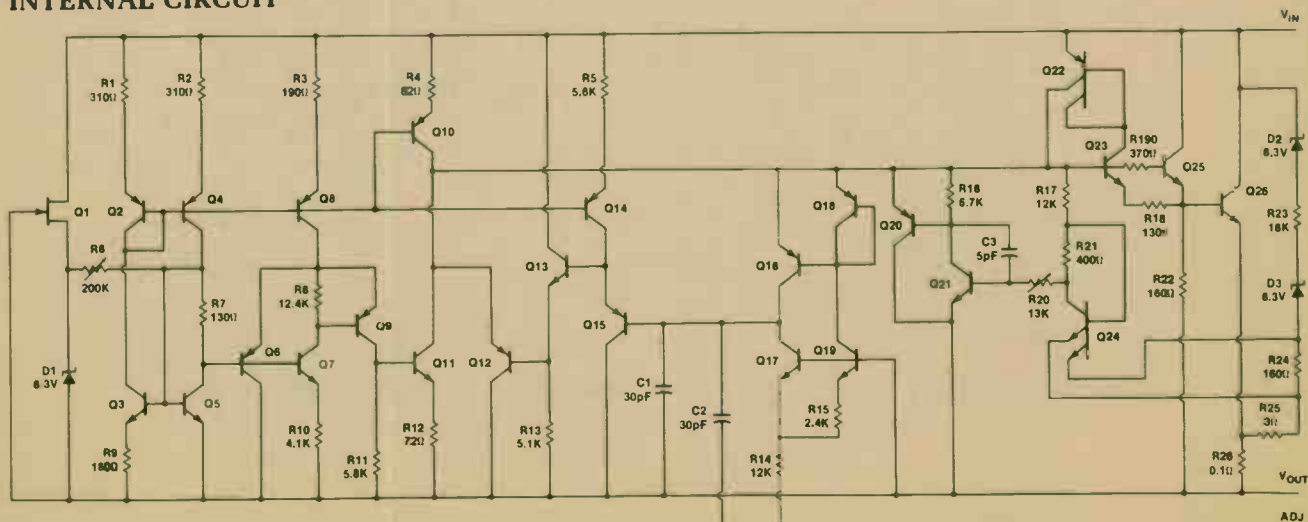

FEATURES

- Adjustable output down to 1.2V
- Guaranteed 1.5A output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- 100% electrical burn-in
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection

5V VOLTAGE REGULATOR

12V VOLTAGE REGULATOR

15V VOLTAGE REGULATOR

GENERAL DESCRIPTION

This series of three terminal regulators is available with several fixed output voltages making them useful in a wide range of applications. One of these is local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow these regulators to be used in logic systems, instrumentation, HiFi, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators these devices can be used with external components to obtain adjustable voltages and currents.

This series will allow over 1.5A load current if adequate heat sinking is provided. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over preventing the IC from overheating.

FEATURES

- Internal thermal overload protection
- No external components required
- Output transistor safe area protection
- Internal short circuit current limit

GENERAL DESCRIPTION

The 339 series consists of four independent voltage comparators which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common-mode voltage range includes ground, even though operated from a single power supply voltage.

FEATURES

LED FLASHER/OSCILLATOR

GENERAL DESCRIPTION

The 3909 is a monolithic oscillator specifically designed to flash light emitting diodes. By using the timing capacitor for voltage boost, it delivers pulses of 2 or more volts to the LED while operating on a supply of 1.5V or less. The circuit is inherently self-starting, and requires addition of only a battery and capacitor to function as a LED flasher.

It has been optimized for low power drain and operation from weak batteries so that continuous operation life exceeds that expected from battery rating.

Application is made simple by inclusion of internal timing resistors and an internal LED current limit resistor.

Timing capacitors will generally be of the electrolytic type, and a small 3V rated part will be suitable for any LED flasher using a supply up to 6V. However, when picking flash rates, it should be remembered that some electrolytics have very broad capacitance tolerances, for example -20% to +100%.

FEATURES

- Operation over one year from one C size flashlight cell
- Bright, high current LED pulse
- Minimum external parts
- Low voltage operation, from just over 1V to 5V
- Low current drain, averages under 0.5 mA during battery life
- Powerful: as an oscillator directly drives an 8Ω speaker

5V LOW-POWER DTMF RECEIVER

SSI202
276-1303

GENERAL DESCRIPTION

The SSI 202 is a complete Dual Tone Multiple Frequency (DTMF) receiver detecting a selectable group of 12 or 16 standard digits. No front-end pre-filtering is needed. The only externally required components are an inexpensive 3.58-MHz television "colorburst" crystal (for frequency reference) and a bias resistor. Extremely high system density is made possible by using the clock output of a crystal connected SSI 202 receiver to drive the time bases of additional receivers. The SSI 202 uses a monolithic integrated circuit fabricated with low-power, complementary symmetry MOS (CMOS) processing. It requires only a single low tolerance voltage supply.

The SSI 202 employs state-of-the-art circuit technology to combine digital and analog functions on the same CMOS chip using a standard digital semiconductor process. The analog input is pre-processed by 60-Hz reject and band splitting filters and then hard-limited to provide AGC. Eight bandpass filters detect the individual tones. The digital post-processor times the tone durations and provides the correctly coded digital outputs. Outputs interface directly to standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures.

FEATURES

- NO front-end band-splitting filters required
- Single, low-tolerance, 5-volt supply
- Detects either 12 or 16 standard DTMF digits
- Uses inexpensive 3.579545-MHz crystal for reference
- Excellent speech immunity
- Output in either 4-bit hexadecimal code or binary coded 2 of 8
- Synchronous or handshake interface
- Three-state outputs

ANALOG IN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated in Fig. 1.

The SSI 202 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental.

CRYSTAL OSCILLATOR

The SSI 202 contains an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal oscillator is enabled by tying XEN high. The crystal is connected between XIN and XOUT. A 1 MΩ 10% resistor is also connected between these pins. In this mode, ATB is a clock frequency output. Other SSI 202's may use the same frequency reference by tying their ATB pins to the ATB of a crystal-connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively. Ten devices may run off a single crystal-connected SSI 202.

IN1633

When tied high, this pin inhibits detection of tone pairs containing the 1633-Hz component. For detection of all 16 standard digits, IN1633 must be tied low.

OUTPUTS D1, D2, D4, D8 and EN

Outputs D1, D2, D4, D8 are CMOS push-pull when enabled (EN high) and open circuited (high impedance) when disabled by pulling EN low. These digital outputs provide the code corresponding to the detected digit in the format programmed by the HEX/B28 pin. The digital outputs become valid after a tone pair has been detected and they are then cleared when a valid pause is timed.

DV and CLRDV

DV signals a detection by going high after a valid tone pair is sensed and decoded at the output pins D1, D2, D4, D8. DV remains high until a valid pause occurs or the CLRDV is raised high, whichever is earlier.

TDA7000

FM RECEIVER

GENERAL DESCRIPTION

The TDA7000 is a monolithic integrated circuit for mono FM portable radios, where a minimum of peripheral components is important (small dimensions and low costs).

The IC has an FLL (Frequency-Locked-Loop) system with an intermediate frequency of 70 kHz. The i.f. selectivity is obtained by active RC filters. The only function which needs alignment is the resonant circuit for the oscillator, thus selecting the reception frequency. Spurious reception is avoided by means of a mute circuit, which also eliminates too noisy input signals. Special precautions are taken to meet the radiation requirements.

The TDA7000 includes the R.F. input stage, mixer, local oscillator, I.F. amplifier/limiter, phase demodulator, mute detector and mute switch.

Circuit with variable-capacitance diode tuning

Since it is only necessary to tune the local-oscillator coil, it is very simple to modify the circuit of Fig. A for variable-capacitance diode tuning. The modifications are shown in Fig. B.

Fig. B Variable-capacitance diode tuning for the local-oscillator. Additional measures must be taken to ensure temperature stability.

Narrow-band f.m. receiver

The TDA7000 can also be used for reception of narrow-band f.m. signals. In this case, the local-oscillator is crystal-controlled as shown in Fig. C and there is therefore hardly any compression of the i.f. swing by the FLL. The deviation of the transmitted carrier frequency due to modulation must therefore be limited to prevent severe distortion of the demodulated audio signal.

The component values in Fig. C result in an i.f. of 4.5 kHz and an i.f. bandwidth of 5 kHz (Fig. D). If the i.f. is multiplied by N, the values of capacitors C₁₇ and C₁₈ in the all-pass filters and the values of filter capacitors C₇, C₈, C₁₀, C₁₀, C₁₁, and C₁₂ must be multiplied by 1/N. For improved i.f. selectivity to achieve greater adjacent channel attenuation, second-order networks can be used in place of C₁₀ and C₁₁.

In this circuit the detuning noise generator is not used. Since the circuit is mainly for reception of audio signals, the audio output must be passed through a low-pass Chebyshev filter to suppress i.f. harmonics.

WORD RECOGNIZER

VCP200
276-1308

SPEAKER-INDEPENDENT WORD RECOGNIZER

GENERAL DESCRIPTION

The VCP200 is a speech recognizer IC that recognizes a limited number of spoken commands, regardless of the person speaking. It identifies commands by breaking the words into broad phoneme classes, and then recognizing pre-determined strings of these classes. The VCP200 performs a spectral analysis of the incoming speech signal over the range of 300 Hz to 5500 Hz, determines the membership of phoneme classes based on spectral shape, forms strings of these classes, and compares the strings to the stored strings of selected commands. The VCP200 recognizes the selected commands, regardless of who spoke them, in real time.

The VCP200 has two speech recognition modes. In the Command Mode, it recognizes five motion commands: *go*, *stop*, *left turn*, *turn right*, and *reverse*. In the Yes-No/On-Off Mode, it recognizes two commands: either *yes* and *no* or *on* and *off*. When the given command is recognized, the associated output for that command provides a latched logic low, capable of sinking up to 10 mA. In the Yes-No/On-Off Mode, a third output indicates no recognition.

The VCP200 is designed for use in a relatively quiet environment. Constant background noise such as fans, air conditioning, or motors can usually be accommodated by adjusting the input amplifier's gain so that the output signal at the second amplifier does not exceed 1 volt peak-to-peak with no speech input. Intermittent noises such as slamming doors, loud music, or construction sounds are harder to deal with. A close-talking, noise-canceling microphone helps, although occasional misrecognition might still occur. In general, the lower the level of outside noises, the better the VCP200 performs.

The location of the microphone relative to the person speaking also affects performance and is dependent on the background noise. The quieter the noise level, the greater the microphone's usable distance. Good performance at up to 2 feet is common for quiet areas. It might help to experiment with several microphones to optimize performance. It might also help to change the frequency/gain characteristics of the input amplifiers to compensate for the high-frequency loss (greater than 4 kHz) as distance increases.

While the VCP200 ignores some words not in its vocabulary, it was designed with the assumption that it need only discriminate among the programmed commands. As a result, words that are not in the VCP200's vocabulary are sometimes identified as being commands, but commands are rarely confused with each other. If the VCP200 must function in the presence of other spoken words, it should be disabled until a command is expected by either bringing Pin 20 low or by using a push-to-talk switch on the microphone.

Application Information

The schematics on the following page provide complete information for implementing the VCP200 in a user application. In addition, a complete printed circuit board layout is provided for construction of a sample circuit.

Note that the values selected for the audio input amplifier cause the amplifier to deliver an extremely clipped square-wave representation of the microphone input. The gain and frequency characteristics of the amplifier can be adjusted to provide better rejection of background noise by selecting the appropriate components.

Once you have constructed a working circuit, there are some things you can do to make the VCP200 work more consistently. It is important that you use the microphone properly. Hold the microphone close to (about 1 inch) and directly in front of your mouth. Point the microphone directly into your mouth so that you are speaking into, rather than across the top of, the microphone. Remember, the final signal into the VCP200 is extremely clipped. It is not a signal that you would input to an amplifier, because the distortion would make the signal nearly unintelligible. You will find that if the VCP200 is having trouble understanding a command, talking louder usually helps, because this causes the signal to clip even more, and provides a sharper transition between phoneme classes. Take the time to experiment with your microphone technique. Once you get this right, you will find that the system operates very well.

As noted earlier, the VCP200 has two different recognition modes. The Command Mode is enabled by bringing Pin 19 low. In this mode, the VCP200 recognizes the commands *go*, *stop*, *reverse*, *left turn*, and *turn right*. The Yes-No/On-Off Mode is enabled by bringing Pin 19 high. In this mode, three outputs indicate the recognition of *yes* or *off*, *no* or *on*, or unrecognized.

Here are a few pointers on how to help the VCP200 understand you better.

GO—Remember that this is a short word. This is the most easily recognized of the five words in the command mode.

LEFT TURN—Note that this command consists of two words. Speak them with a normal separation between the words, and pronounce both t's.

TURN RIGHT—This command also consists of two words. For this command, however, try running the words together. Also, emphasize the beginning and ending t's. If the VCP200 confuses this command with LEFT TURN, try speaking a little louder.

REVERSE—This is the most difficult word for the VCP200 to properly recognize. Be sure to pronounce the first e and slightly emphasize the final s.

STOP—Emphasize each of the four sounds that make up this word; especially the initial s and the final p.

In the Yes-No/On-Off Mode, the VCP200 has virtually no trouble distinguishing between the two words. This mode works with either word pair because of the similarity between yes and off, and between on and no. Be sure to pronounce the final sound ("sss" or "fff") in yes and off, and you should have no problem.

The first few times you use the VCP200 you might have a little trouble. Just as it is difficult to understand someone that pronounces words a little differently, your VCP200 might not be able to understand you at first. The difference here is that the VCP200 cannot learn new pronunciations or new words. It is up to you to learn to pronounce the words in a way that the VCP200 can understand. The good thing is that the VCP200 definitely does understand you, once you learn to pronounce the commands correctly.

THEORY OF OPERATION

Your VCP200 uses a technique called *speaker-independent speech recognition*. Speaker-independent means that the VCP200 is designed so that there is a very high probability that it can understand anyone who can properly pronounce the words in its vocabulary. This differs significantly from the more common form of speech recognition which is called *speaker-dependent speech recognition*. In speaker-dependent speech recognition, a user must go through a long training process to teach the machine to recognize the words. After training, the machine can recognize that person with a high degree of accuracy, but it does not do nearly as well when a person other than the one that trained it tries to use it, or even when the person that trained it is hoarse. Also, with speaker-dependent recognition, the training must be repeated if, for some reason, electrical power is removed from the microprocessor. You never have to train your VCP200. It never forgets the words it is programmed to understand.

THEORY OF OPERATION CONT'D.

Basically, the success of speaker-independent speech recognition depends on two factors. The first factor is that a properly pronounced word, after analysis, gives a very similar pattern regardless of who says the word. The second factor is that the words your device is trying to recognize must sound as different as possible, while still being consistent with the purposes of the device. This is the reason you must say "left turn" and "turn right." If "turn" had come first for both commands, it would have been much more difficult to tell the two commands apart.

Any device designed to perform speaker-independent speech recognition is programmed with only a few words. When it hears a word, it searches through its set to see if the word is one it recognizes. If there is any question, it either rejects the word or picks the command that sounds closest to what it received. This is why it is important in the design to pick words that sound different. This means that when you try to fool the VCP200 you will succeed, because it was not designed to recognize all words. It was designed to recognize specific words.

TYPICAL APPLICATION

Notes:

1. Always jumper Pin 18 to ground.
2. Do not connect jumper for Pins 16 and 17.
3. An SPST switch on Pin 19 to ground allows you to easily change the mode.
4. If you use a 9-volt supply, you only need the 7805. If you use a 6-volt supply, you only need CR1. You do not need to connect both.
5. If the ambient noise level is low, $R_4 = 30K$, $R_{10} = 10K$, $R_{11} = 10K$ lessens the need to speak loudly.
6. R_4 sets the audio gain and might need to be adjusted, depending on the sensitivity of the microphone you select.

This circuit provides latched outputs for GO and REVERSE. This lets you combine GO or REVERSE with LEFT TURN or TURN RIGHT. Be sure to STOP before switching between GO and REVERSE.

IMPORTANT SUGGESTIONS ON THE USE AND REPLACEMENT OF TRANSISTORS

You can use various styles and sizes of transistors in any given circuit application, as long as the electrical characteristics of the device are within the required range of operation. Thus, a tab-type device can be used to replace a TO-3 or TO-66 case device; or a small epoxy-type device can be used in place of TO-5 or other size transistor.

Generally speaking, you must observe the following maximum characteristics of a transistor when contemplating substitution or selection:

- Power dissipation
- Maximum collector current
- Maximum collector-to-emitter voltage
- Maximum collector-to-base voltage
- Maximum emitter-to-base voltage

Also, it is useful to consider the following characteristics for actual circuit operation:

- Gain
- Frequency limitations

Caution: It may be necessary in some cases to adjust bias values to achieve required operation. With tuned circuits, it is a good practice to check alignment after replacing any transistor.

When replacing power transistors, always check driver devices to be sure they are OK. Also, check other circuit components to be sure they were not shorted (or otherwise defective) when the original device failed. If you fail to correct such problems before applying power to the circuit once again, the replacement transistor could easily be permanently damaged. Be sure to use proper heat-sink precautions and use silicon grease to reduce the thermal resistance between the case of the transistor and the heat-sink.

Always observe temperature limitations as specified with transistor ratings.

It almost goes without saying, but let us remind you anyway—

Always observe voltage polarity with all semiconductor devices.

CROSS-REFERENCE/SUBSTITUTION LISTING

Most users of semiconductors realize that it is almost impossible to guarantee absolute equivalents (as in the case of tubes). Thus, the only way to create replacement or cross-reference listings is by carefully evaluating each characteristic of both devices (original transistor and the possible alternate). This is how the Technical Staff of Radio Shack went about preparing the following cross-reference/replacement lists.

IMPORTANT NOTE

We caution you that in many cases the listed cross reference ARCHER device may be different in appearance, size or mounting style. Thus, before beginning replacement or installation procedures, check to be sure you have enough room for proper mounting.

Also, when making substitutions or replacements in radio or high frequency circuitry, it may be necessary to realign tunable circuit elements. This is true even

when making exact replacements (junction capacitances normally vary between devices even from the same production run).

INTRODUCTION

This SEMICONDUCTOR REFERENCE HANDBOOK is intended to be just that—a reference handbook. It is not a definitive text book on semiconductors. It is a compilation of data on Radio Shack's line of prime-quality ARCHER[®] semiconductors. Every ARCHER device covered in this Handbook is guaranteed prime—they are not "fall-outs" or "seconds"; all are top-quality, with known JEDEC, EIA or manufacturer's numbers.

At the back of the book is a cross-reference listing for replacement of Transistors, Diodes and other interchangeable semiconductor devices. The total number of cross-referenced devices exceeds 94,000. These cross-reference/replacement listings are computer-selected and are based on careful analysis of important parameters of the listed devices.

NOTE: If you can't find a replacement listing for a device you require, refer to the specification listings of the appropriate ARCHER family device. Often you will be able to make suitable replacements based on the information presented.

Each ARCHER replacement should meet or exceed the required parameters. However, due to differences in Quality Control and Manufacturing procedures (which often allow for or result in broad parameter variations), and because many of the ARCHER devices are capable of better performance than the original, Radio Shack does not guarantee, nor does it imply, that the listed items will provide an exact replacement in every instance. Therefore we recommend that you check the voltage and current requirements of the circuit (and other pertinent specifications) before replacement and compare with the specifications listed for that particular ARCHER device.

HOW TO USE THIS BOOK

This book has been prepared to aid in BOTH replacement and original applications of Semiconductor devices. The information included will be invaluable for the service technician as well as the circuit designer (whether he be an engineer, hobbyist, student or electronics experimenter).

We have included hints on handling Semiconductor devices, operating considerations, and some simple tests to aid you in evaluating the quality of the device in existing equipment (and thus the need for replacement). Also, a complete section on the specifications for each of the ARCHER devices is included; if there is any question in your mind about replacement equivalents or original use, refer to the appropriate category in the book. You will find the important characteristics specified there.

The next to last section is an extensive listing of replacement and cross reference between other manufacturer's numbers (both JEDEC/EIA 2N—numbers and in-house designations) and the ARCHER devices. This listing provides for the substitution of over 94,000 semiconductors with ARCHER devices.

The final section includes case style drawings and some handy reference notes, a comprehensive glossary of commonly used words, plus symbols and abbreviations.

CARE AND HANDLING OF TRANSISTORS

Most modern transistors are somewhat immune from mechanical shock; however, it is always a good idea to keep them from excessive mechanical shocks, especially the metal-case type (avoid dropping, etc).

When cutting transistor leads, use scissor-type cutting tools (rather than diagonal cutting tools which use a crimping action). Crimp-type cutting tools produce a mechanical shock along the lead which when transmitted to the semiconductor chip or material can cause fracture. Consider the force with which the cut lead flies off the crimp-type cutting tool and you have a good idea of the intensity of the equal and opposite force which acts on the lead going into the device.

It is always a good practice to use a heat-sink tool on a transistor lead when soldering (use a low-wattage iron—30-watts or less). Heat from soldering can cause problems (especially with certain types of semiconductor devices). Thus, to be sure, always use a heat-sink on the lead when soldering. Gripping the lead with long nose pliers between the solder connection and the case of the device makes a good heat-sink; or use a tool designed for such use.

SILICON OR GERMANIUM?

The quickest way to determine if a transistor is germanium or silicon type, is to check the normal emitter-base voltage drop. With NPN devices, if the base is approximately 0.25 volts positive with respect to the emitter, it is a germanium type. If the voltage is about 0.65 volts, it is a silicon type. For PNP devices, the voltage will be the same value, but opposite in polarity (0.25 volts for germanium and 0.65 for silicon).

OPERATING CONSIDERATIONS

Before replacing an original-equipment device with the recommended Archer Type:

(A) Compare the lead or terminal arrangement of the Archer replacement device with the lead or ter-

minal arrangement of the original device. If these arrangements are different, and the original transistor is a "plug in" type, bend the leads of the ARCHER device so that the base, emitter and collector leads will mate with the original transistor leads. Trim the leads after soldering in place.

CAUTION: Be particularly careful about "pin-circle" and "in-line" lead break-out type transistors. Often one manufacturer makes a type with "in-line" leads, while another may make the same type with "pin-circle" configuration. **Doublecheck both the original and the replacement device before soldering or plugging in transistors.**

IN-LINE

(B) Certain considerations are involved whenever an original equipment transistor is replaced by one having a different type designation. When an ARCHER series transistor is used to replace an original equipment device in an untuned amplifier stage operating at a low signal level such as the untuned RF-amplifier (antenna) stage of a radio receiver, or a low-level AF amplifier stage, it is generally unnecessary to make any circuit adjustment to assure proper performance of the equipment. However, when a replacement is made in a turned RF amplifier stage, it is always advisable to check the alignment of the associated tuned circuits to assure proper tracking and to achieve the required gain without loss of stability.

(C) When replacements are made in stages operating at relatively high power levels, such as Class A and Class B AF output stages of automobile radio receivers, phonographs and AF-amplifier systems, the transistor bias should be checked and adjusted, if necessary, to protect the ARCHER replacement transistors against excessive dissipation and to minimize distortion. Means for making adjustments are generally provided in the equipment, and the necessary instructions are usually given in the equipment manufacturer's service data.

(D) When installing an ARCHER transistor as a substitute for an original equipment type in an FM tuner, TV tuner, or other circuits operating at frequencies in the VHF or UHF regions, it is extremely important not to change any of the lead lengths or position of the original circuit. Before removing the original transistor, carefully note its position with respect to other circuit components as well as the lengths and placement of the transistor leads, and duplicate these details as closely as possible with the ARCHER replacement transistor. Failure to observe this precaution can result in improper tuning or circuit instability. The same holds true for any replacement of Integrated Circuits, specially in FM radios and TV Receivers. Failure to

observe this precaution can result in damage in the device. Transistor substitution in tuned circuits will often require realignment of the circuit.

SILICON VS SELENIUM RECTIFIERS

Silicon rectifiers are inherently more efficient than selenium or other metallic-oxide type rectifiers. When a silicon rectifier is used to replace a selenium rectifier in the power supply of a typical line-operated radio or TV receiver, the silicon rectifier will frequently deliver higher DC output voltage than the original device.

In some cases, this higher supply voltage may improve the performance of the equipment. However, in many other cases, it may immediately or eventually damage filter capacitors and/or other components which were designed to withstand only the voltage delivered by the original selenium rectifier. To prevent such damage, it is generally advisable to insert a power type resistor in series with the silicon rectifier either on the input side, between the AC supply and the rectifier, or on the output side between the rectifier and the first filter capacitor. The value of this resistor will depend on the required reduction in the DC output voltage and on the DC load current of the equipment. This value may be determined experimentally or calculated from the equation:

$$R = \frac{E}{I}$$

where R is the required resistance in ohms, E the required reduction in DC output voltage in volts and I the DC load current in amperes.

The wattage rating of the resistor should be at least $2 \times EI$ (in no case less than 10 watts).

SOLDERING PRECAUTIONS

Extreme care should always be used in making solder connections to semiconductors. Momentary application of excessive heat, or even prolonged application of a properly heated soldering tool to a semiconductor lead or terminal, can permanently damage the device. Observe the following precautions in soldering a semiconductor lead or terminal:

1. Solder as far as possible from the body of the semiconductor.
2. Never, apply heat or molten solder to a lead or terminal for longer than 10 seconds or at a point closer than 1/16 inch to the body of the device.
3. Use a low voltage iron (30 watts or less) specifically intended for use with transistors or miniature circuit components.
4. Keep the surfaces to be soldered clean and the tip of the soldering tool adequately tinned so that the connection can be made as quickly as possible.
5. Always use a heat sink on the lead when soldering. Gripping the lead or terminal with longnose pliers between the solder connection and case or body allows the pliers to act as a heat sink, conducting heat away from the internal elements of the device.

ABOUT CASE DIMENSIONS

In some instances, the case of an ARCHER Semi-

conductor may be slightly taller or thicker than that of the original device or have a slightly different shape, particularly if the original device is a foreign type not made to U.S.A. EIA (JEDEC) standards. These mechanical differences should not affect the performance of the equipment in which the replacement is made and normally will not prevent or complicate the installation of the ARCHER replacement device.

You should realize that cross-reference substitution listings are created based on **electrical parameters (not necessarily on mechanical size or type)**. Thus, when you make substitutions based on our listings, check for physical/mechanical compatibility. If space is limited, it would be a good idea to check physical dimensions as well as electrical specs before making substitution.

GENERAL PRECAUTIONS

ARCHER transistor and ARCHER semiconductors should not be inserted or withdrawn from circuits with the power on, because transient currents may cause permanent damage to the device. In some cases ARCHER semiconductors are in metal cans and thus could possibly become shock hazards if they are allowed to operate at a voltage appreciably above or below ground potential.

For the most effective protection, a power transistor should be operated with an adequate heat sink and with the lowest value of resistance or impedance in the emitter-to-base circuit consistent with driving signal considerations. The transistor should be protected against extremely high collector voltage pulses which may be generated when the device is operated with inductive loads particularly when current transients are present.

When replacing a power transistor or rectifier which is attached to the equipment chassis, or to a special heat sink, observe the following precautions:

A. In the case of oxide coated metal washers or wafers, which are frequently used as electrical insulators between the cases of power transistors and the chassis or heat sink, it is important not to scratch, chip or otherwise damage the oxide surface.

B. When installing an ARCHER power transistor, where a mica or oxide coated metal washer was used to insulate the case of the original device electrically from the case, apply a thin coating of Heat Sink Compound (Radio Shack Number 276-1372) between the washer and the chassis or heat sink.

TESTING A TRANSISTOR

Before replacing a transistor you want to be sure it needs to be replaced. Always check the entire circuitry to be sure the transistor requires replacement.

The best method for checking transistors is to use a good transistor checker (dynamic in-circuit and out-of-circuit type). However, a sensitive VOM can give you a good indication of the quality of the device.

I. In-Circuit Testing

A. First, check to see if the emitter-base junction is

forward-biased. An NPN transistor should show the base 0.2 to 0.65 volts positive with respect to the emitter (approximately 0.25 volts for a germanium type and 0.6 volts for silicon). A PNP transistor should show the base 0.2 to 0.65 volts negative with respect to the emitter (0.25 volts for germanium and 0.6 volts for silicon).

B. Check to see if the device is functioning as an amplifier. Short the emitter-base junction to remove forward bias. Voltage at the collector lead should rise to approximately the potential of the collector supply buss line. Any difference is caused by ICES (collector-to-base leakage current). The closer the collector voltage approaches the buss line, the lower ICES is and the better the transistor.

II. Out-of-Circuit Testing

Again, for the best indication of transistor quality, use a good transistor checker. However, an ohmmeter can be used as described here.

Before using the ohmmeter, find out which polarity of the internal ohmmeter battery is connected to which test lead (not all ohmmeters have the + battery polarity connected to the red lead and the - battery polarity connected to the black lead). To determine the polarity of the leads when using the ohmmeter function, use an external voltmeter or study the schematic of your VOM.

Also, remember that in most transistor circuits you are dealing with low voltages and currents (in some cases, very low). Therefore, NEVER use RX1 scale (extensive currents can flow through a junction, permanently damaging the transistor). It is best to determine the maximum amount of current available in each resistance range before using an ohmmeter for testing semiconductor junctions.

After you have evaluated your VOM for the above and are sure you will not damage a transistor (with excessive current or voltage in any given ohmmeter range), proceed as follows:

- A. Small Signal PNP Germanium Transistors
 1. Connect the positive lead of your ohmmeter to the emitter. Connect the negative lead to the base. You should read 200-500 ohms.
 2. Connect the negative lead to the collector. You should read 10K-100K. Shorting collector base, the resistance should decrease.
- B. Small Signal NPN Germanium Transistors
Reverse the polarity of the leads; the readings should be approximately the same.
- C. Power PNP Germanium Transistors
 1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 35-50 ohms.
 2. Connect the negative lead to the collector. The reading should be several hundred ohms. Shorting collector to base, the resistance should decrease.
- D. Power NPN Germanium Transistors
Reverse the polarity of the leads; the reading should be approximately the same.

E. Small Signal PNP Silicon Transistors

1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 1K-3K.
2. Connect the negative lead to the collector. The reading should be very high (may show as an "open").

F. Small Signal NPN Silicon Transistors

Reverse the polarity of the leads; the readings should be approximately the same.

G. Power PNP Silicon Transistors

1. Connect the positive lead to the emitter. Connect the negative lead to the base. The reading should be 200-1K.
2. Connect the negative lead to the collector. The reading should be about 1 megohm or more.

H. Power NPN Silicon Transistors

Reverse the polarity of the leads; the readings should be approximately the same.

The resistance readings noted above can only be approximate; as long as you obtain somewhat proportionate readings (emitter-base readings as compared to emitter-collector), you can safely assume the transistor is OK.

HANDLING OF INTEGRATED CIRCUITS

Because MOS devices have extremely high input resistance, they are susceptible to damage when exposed to static electrical charges (even electrical charges that normally build up on the human body can cause damage). To avoid possible damage to the devices during handling, testing, or actual operation, the following procedures should be observed:

1. Except when being tested or in actual operation, the leads of devices should be in contact with a conductive material, to avoid build-up of static charge.
2. Soldering iron tips, tools, metal parts of fixtures and handling facilities should be grounded.
3. Transient voltages may cause permanent damage to the device if it is removed or inserted with the power on.
4. Do not apply signals to the input with the power supply off.
5. All unused input leads must be connected to either VSS or VDD (whichever is appropriate for the logic circuit involved).

GENERAL DESCRIPTION

ZNR varistors are zinc oxide resistors whose resistance changes as a function of the applied voltage. The ZNR has a bilateral and symmetrical V-I characteristic curve and can therefore be used in circuits in place of back-to-back zener diodes. This gives your circuit clamping protection in either direction. The ZNR provides a highly reliable and economical way to protect against repeated high voltage transients and surges such as those produced by lightning, switching surges and noise spikes.

FEATURES

- Excellent clamping voltage characteristic and fast response time (< 50 nsec.) when subjected to impulse surges. Eliminates the discharge lag that is indicative of gap-type arrestors.
- Bilateral and symmetrical V-I characteristic curve. The ZNR can, therefore, be used both in AC and in DC circuits, for protection of either positive or negative transients.

THYRISTORS

MU27

GENERAL DESCRIPTION

Thyristors and their trigger devices can take numerous forms, but they share these characteristics:

- They are "open circuits," capable of withstanding rated voltage until triggered.
- They become low-impedance current paths when triggered, and remain so, even after the trigger source is removed, until current through that path stops, or is reduced below a minimum "holding" level.

SCRs

Silicon-Controlled Rectifiers (SCRs) are Thyristors intended to switch load currents in one direction only, making them useful for DC and half-wave AC applications as well as full-wave applications, in which bidirectional current is routed in one direction through the SCR via a bridge rectifier.

TRIACs

Triacs are bidirectional Thyristors, in which a single trigger source turns the device on for load current in either direction. Because they do not require a bridge rectifier in order to handle full-wave AC, Triacs are useful in AC power applications that require full source power control capability to be applied to the load.

TRI-COLOR LIGHT EMITTING DIODE

XC-5491
276-035

GENERAL DESCRIPTION

The XC-5491 tri-state LED provides red, green, and yellow emission in the same package. This LED is a popular .200 diameter, two-lead package containing a red and green LED chip in inverse parallel. By reversing the polarity of the applied current, the LED will emit red or green light while an AC voltage results in yellow light. The chips used in the XC-5491 are brightness matched so that the light output is uniform. This eliminates the necessity for the special drive circuits previously required with tri-state lamps.

These lamps provide the designer with the capability of efficiently displaying three functions with one indicator. This reduces the number of front panel indicators and simplifies design.

2.5×5cm SILICON SOLAR CELL

GENERAL DESCRIPTION

A solar cell is a silicon semiconductor device which converts light energy directly to electricity. A typical 2.5×5cm cell will produce 0.42 volt and up to .18 amp of usable current. The power generated is affected by the load resistance (circuit powered by cell) strength of sunlight and temperature.

Be extremely careful when soldering leads. Use only a very fine wire (#26 or thinner) and use a small soldering iron (less than 50 watts). Solar cells may be connected in series to produce more voltage and in parallel for more current.

DECADE COUNTER/DIVIDER

GENERAL DESCRIPTION

The 4017 is a five-stage Johnson decade counter with built-in code converter. High-speed operation and spike-free outputs are obtained by use of a Johnson decade counter design. This part can be used in frequency division applications as well as decade counter or decimal decode display applications.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$.

65,536-BIT DYNAMIC RANDOM ACCESS MEMORY (RAM)

HYB4164-P2
276-2506

GENERAL DESCRIPTION

The HYB4164 is a 65536-word by 1-bit, MOS random access memory circuit fabricated with new 5-volt only n-channel silicon gate technology, using double layer polysilicon. To protect the chip against α -radiation a chip cover is used. The HYB4164 uses single transistor dynamic storage cells and dynamic control circuitry to achieve high speed at very low power dissipation. Multiplexed address inputs permit the HYB4164 to be packaged in an industry standard 16-pin dual-in-line package.

System oriented features include single power supply with $\pm 10\%$ tolerance, on-chip address and data latches which eliminate the need for interface registers and fully TTL compatible inputs and outputs, including clocks.

In addition to the usual read, write and read-modify-write cycles, the HYB4164 is capable of early and delayed write cycles, RAS-only refresh and hidden refresh. Common I/O capability is given by using "early write" operation.

FUNCTIONAL DESCRIPTIONS

Addressing (A_0 - A_7)

For selecting one of the 65536 memory cells, a total of 16 address bits are required. First 8 row-address bits are setup on pins A_0 through A_7 and latched onto the row address latches by the Row Address Strobe ($\overline{\text{RAS}}$). Then the 8 column-address bits are set-up on pins A_0 through A_7 and latched onto the column address latches by the Column Address Strobe ($\overline{\text{CAS}}$). All input addresses must be stable on or shortly after the falling edge of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ respectively. $\overline{\text{CAS}}$ is internally gated by $\overline{\text{RAS}}$ to permit triggering of column address latches as soon as the Row Address Hold Time (t_{RAH}) specification has been satisfied and the address inputs have been changed from row-address to column-address.

It should be noted that $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip-select activating the column decoder and the input and output buffers.

TYPICAL CHARACTERISTICS

Current Consumption During Power Up (V_{CC} Risettime $10\mu s$)

Current Consumption During Power Up (V_{CC} Risettime $100\mu s$)

FUNCTIONAL DESCRIPTIONS (Cont'd)

Write Enable (\overline{WE})

The read or write mode is selected with the \overline{WE} input. A logic high (V_{IH}) on \overline{WE} dictates read mode; logic low (V_{IL}) dictates write mode. The data input is disabled when the read mode is selected. When \overline{WE} goes low prior to \overline{CAS} , data output (DO) will remain in the high-impedance state for the entire cycle permitting common I/O operation.

Data Input (DI)

Data is written during a write or read-modify-write cycle. The falling edge of \overline{CAS} or \overline{WE} strobbs data into the on-chip data latch. In an early write cycle \overline{WE} is brought low prior to \overline{CAS} and the data is strobbed in by \overline{CAS} with set-up and hold times referenced to this signal. In a delayed write or read-modify write cycle, \overline{CAS} will already be low, thus the data will be strobbed in by \overline{WE} with set-up and hold times referenced to this signal.

Power ON

An initial pause of $200\mu s$ is required after power-up followed by a minimum of eight (8) initialization cycles (any combination of cycles containing a \overline{RAS} clock such as \overline{RAS} -only refresh) prior to normal operation. The current requirement of the HYB4164 during power on is, however, dependent upon the input levels \overline{RAS} , \overline{CAS} and the rise time of V_{CC} , as shown in the (Current Consumption During Power Up) diagram.

Data Output (DO)

The output buffer is three-state TTL compatible with a fan-out of two standard TTL loads. Data-out is the same polarity as data-in. The output is in a high-impedance state until \overline{CAS} is brought low. In a read cycle, or read-write cycle, the output is valid after t_{RAC} from the transition of \overline{RAS} when t_{RCD} (min) is satisfied, or after t_{CAC} from the transition of \overline{CAS} when the transition occurs after t_{RCD} (max.). \overline{CAS} going high returns the output to a high-impedance state. In an early write cycle the output is always in the high-impedance state. In a delayed write or read-modify-write cycle, the output will follow the sequence for the read cycle.

FUNCTIONAL DESCRIPTIONS (Cont'd)

Hidden Refresh

RAS only refresh cycle may take place while maintaining valid output data. This feature is referred to as Hidden Refresh. Hidden Refresh is performed by holding CAS at V_{IL} from a previous memory read cycle.

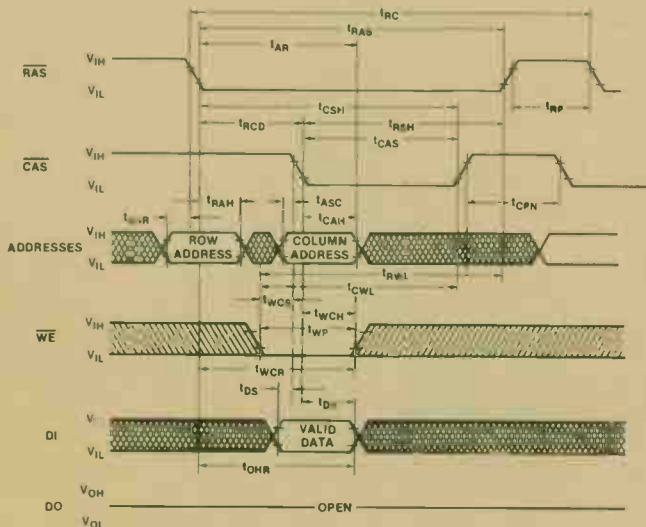

Page Mode

Page Mode operations allows a faster data transfer rate. This is achieved by maintaining the row address while strobing successive column addresses onto the chip. The time required to set-up and strobe sequential row addresses for the same page is eliminated.

Refresh Cycle

A refresh operation must be performed at least every four milli-seconds to retain data. Since the output buffer is in the high-impedance state unless CAS is applied, the RAS only refresh sequence avoids any output signal during refresh. Strobing each of the 256 row addresses (A_0 through A_7) with RAS causes all bits in each row to be refreshed. CAS can remain high (inactive) for this refresh sequence to conserve power.

256 K DYNAMIC RAM

GENERAL DESCRIPTION

The 4256 is a high-speed, 262,144-bit dynamic random-access memory, organized as 262,144 words of one bit each. It employs state-of-the-art SMOS (scaled MOS) N-channel double-level polysilicon/polycide gate technology for very high performance combined with low cost and improved reliability.

This device features maximum RAS access times of 150ns. Typical power dissipation is as low as 275 mW operating and 12.5 mW standby.

New SMOS technology permits operation from a single 5-V supply, reducing system power supply and decoupling requirements, and easing board layout. I_{DD} peaks are 125 mA typical, and -1-V input voltage undershoot can be tolerated, minimizing system noise considerations.

All inputs and outputs, including clocks, are compatible with Series 74 TTL. All address and data-in lines are latched on chip to simplify system design. Data out is unlatched to allow greater system flexibility.

OPERATION

address (A0 through A8)

Eighteen address bits are required to decode 1 of 262,144 storage cell locations. Nine row-address bits are set up on pins A0 through A8 and latched onto the chip by the row-address strobe ($\overline{\text{RAS}}$). Then the nine column-address bits are set up on pins A0 through A8 and latched onto the chip by the column-address strobe ($\overline{\text{CAS}}$). All addresses must be stable on or before the falling edges of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. $\overline{\text{RAS}}$ is similar to a chip enable in that it activates the sense amplifiers as well as the row decoder. $\overline{\text{CAS}}$ is used as a chip select activating the column decoder and the input and output buffers.

write enable ($\overline{\text{W}}$)

The read or write mode is selected through the write-enable ($\overline{\text{W}}$) input. A logic high on the $\overline{\text{W}}$ input selects the read mode and a logic low selects the write mode. The write-enable terminal can be driven from standard TTL circuits without a pull-up resistor. The data input is disabled when the read mode is selected. When $\overline{\text{W}}$ goes low prior to $\overline{\text{CAS}}$, data out will remain in the high-impedance state for the entire cycle permitting common I/O operation.

data in (D)

Data is written during a write or read-modify-write cycle. Depending on the mode of operation, the falling edge of $\overline{\text{CAS}}$ or $\overline{\text{W}}$ strobes data into the on-chip data latch. This latch can be driven from standard TTL circuits without a pull-up resistor. In an early write cycle, $\overline{\text{W}}$ is brought low prior to $\overline{\text{CAS}}$ and the data is strobed in by $\overline{\text{CAS}}$ with setup and hold times referenced to this signal. In a delayed-write or read-modify-write cycle, $\overline{\text{CAS}}$ will already be low, thus the data will be strobed in by $\overline{\text{W}}$ with setup and hold times referenced to this signal.

data out (Q)

The three-state output buffer provides direct TTL compatibility (no pull-up resistor required) with a fan out of two Series 74 TTL loads. Data out is the same polarity as data in. The output is in the high-impedance (floating) state until $\overline{\text{CAS}}$ is brought low. In a read cycle the output goes active after the access time interval $t_{a(R)}$ that begins with the negative transition of $\overline{\text{CAS}}$ as long as $t_{a(R)}$ is satisfied. The output becomes valid after the access time has elapsed and remains valid while $\overline{\text{CAS}}$ is low; $\overline{\text{CAS}}$ going high returns it to a high-impedance state. In a read-modify-write cycle, the output will follow the sequence for the read cycle.

refresh

A refresh operation must be performed at least once every four milliseconds to retain data. This can be achieved by strobing each of the 256 rows (A0-A7). A normal read or write cycle will refresh all bits in each row that is selected. A $\overline{\text{RAS}}$ -only operation can be used by holding $\overline{\text{CAS}}$ at the high (inactive) level, thus conserving power as the output buffer remains in the high-impedance state.

$\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh

The $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh is utilized by bringing $\overline{\text{CAS}}$ low earlier than $\overline{\text{RAS}}$ (see parameter t_{CRL}) and holding it low after $\overline{\text{RAS}}$ falls (see parameter t_{CLR}). For successive $\overline{\text{CAS}}$ -before- $\overline{\text{RAS}}$ refresh cycles, $\overline{\text{CAS}}$ can remain low while cycling $\overline{\text{RAS}}$. The external address is ignored and the refresh address is generated internally.

hidden refresh

Hidden refresh may be performed while maintaining valid data at the output pin. This is accomplished by holding $\overline{\text{CAS}}$ at V_{IL} after a read operation and cycling $\overline{\text{RAS}}$ after a specified precharge period, similar to a " $\overline{\text{RAS}}$ -only" refresh cycle. The external address is also ignored during the hidden refresh cycles.

page mode

Page-mode operation allows effectively faster memory access by keeping the same row address and strobing random column addresses onto the chip. Thus, the time required to setup and strobe sequential row addresses for the same page is eliminated. The maximum number of columns that can be addressed is determined by t_{WR} , the maximum $\overline{\text{RAS}}$ low pulse duration.

power-up

To achieve proper device operation, an initial pause of 200 μs is required after power up followed by a minimum of eight initialization cycles.

Two possible ways at handling unused inputs are:

DIVIDE BY 2 OR 5, BCD COUNTER

GENERAL DESCRIPTION

This monolithic BCD counter contains four master-slave flip-flops and additional gating to provide a divide-by-two counter and a three-stage binary counter for which the count cycle length is divide-by-five.

This counter has a gated zero reset and gated set-to-nine inputs for use in BCD nine's complement applications.

To use maximum count length, the B input is connected to the Q_A output. The input count pulses are applied to input A and the outputs are as described in the appropriate truth table. A symmetrical divide-by-ten count can be obtained from the 90 counter by connecting the Q_D output to the A input and applying the input count to the B input which gives a divide-by-ten square wave at output Q_A.

APPLICATIONS INFORMATION

The Electronic Industries Association (EIA) RS232C specification detail the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The 1488 quad driver and its companion circuit, the 1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the RS232C defined levels. The RS232C requirements as applied to drivers are discussed herein.

The required driver voltages are defined as between 5 and 15-volts in magnitude and are positive for a logic "0" and negative for a logic "1". These voltages are so defined when the drivers are terminated with a 3000 to 7000-ohm resistor. The 1488 meets this voltage requirement by converting a DTL/TTL logic level into RS232C levels with one stage of inversion.

The RS232C specification further requires that during transitions, the driver output slew rate must not exceed 30 volts per microsecond. The inherent slew rate of the 1488 is much too fast for this requirement. The current limited output of the device can be used to control this slew rate by connecting a capacitor to each drive output. The required capacitor can be easily determined by using the relationship $C = I_{OS} \times \Delta T / \Delta V$ from which Figure 1 is derived. Accordingly, a 330-pF capacitor on each output will guarantee a worst case slew rate of 30 volts per microsecond.

The interface driver is also required to withstand an accidental short to any other conductor in an interconnecting cable. The worst possible signal on any conductor would be another driver using a plus or minus 15-volt, 500-mA source. The 1488 is designed to indefinitely withstand such a short to all four outputs in a package as long as the power-supply voltages are greater than 9.0 volts (i.e., $V_{CC} \geq 9.0 V$; $V_{EE} \leq -9.0 V$). In some power-supply designs, a loss of system power causes a low impedance on the power-supply outputs. When this occurs, a low impedance to ground would exist at the power inputs to the 1488 effectively shorting the 300-ohm output resistors to ground. If all four outputs were then shorted to plus or minus 15 volts, the power dissipation in these resistors would be excessive. Therefore, if the system is designed to permit low impedances to ground at the power-supplies of the drivers, a diode should be placed in each power-supply lead to prevent overheating in this fault condition. These two diodes, as shown in Figure 2, could be used to decouple all the driver packages in a system. (These same diodes will allow the 1488 to withstand momentary shorts to the ± 25 -volt limits specified in the earlier Standard RS232E.) The addition of the diodes also permits the 1488 to withstand faults with power-supplies of less than the 9.0 volts stated above.

The maximum short-circuit current allowable under fault conditions is more than guaranteed by the previously mentioned 10 mA output current limiting.

OTHER APPLICATIONS

The 1488 is an extremely versatile line driver with a myriad of possible applications. Several features of the drivers enhance this versatility:

1. Output Current Limiting—this enables the circuit designer to define the output voltage levels independent of power-supplies and can be accomplished by diode clamping of the output pins. Figure 14 shows the 1488 used as a DTL to MOS translator where the high-level voltage output is clamped one diode above ground. The resistor divider shown is used to reduce the output voltage below the 300 mV above ground MOS input level limit.

2. Power-Supply Range—as can be seen from the schematic drawing of the drivers, the positive and negative driving elements of the device are essentially independent and do not require matching power-supplies. In fact, the positive supply can vary from a minimum seven volts (required for driving the negative pulldown section) to the maximum specified 15 volts. The negative supply can vary from approximately -2.5 volts to the minimum specified -15 volts. The 1488 will drive the output to within 2 volts of the positive or negative supplies as long as the current output limits are not exceeded. The combination of the current-limiting and supply-voltage features allow a wide combination of possible outputs within the same quad package. Thus if only a portion of the four drivers are used for driving RS232C lines, the remainder could be used for DTL to MOS or even DTL or DTL translation. Figure 15 shows one such combination.

APPLICATIONS INFORMATION

The Electronic Industries Association (EIA) has released the RS-232C specification detailing the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The 1488 quad driver and its companion circuit, the 1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the RS-232C defined levels. The RS-232C requirements as applied to receivers are discussed here. The required input impedance is defined as between 3000 ohms and 7000 ohms for input voltages between 3.0 and 25 volts in magnitude; and any voltage on the receiver input in an open circuit condition must be less than 2.0 volts in magnitude. The 1489 circuits meet these requirements with a maximum open circuit voltage of one V_{BE} .

The receiver shall detect a voltage between -3.0 and -25 volts as a logic "1" and input between $+3.0$ and $+25$ volts as a logic "0". On some interchange leads, an open circuit or power "OFF" condition (300 ohms or more to ground) shall be decoded as an "OFF" condition or logic "1". For this reason, the input hysteresis thresholds of the 1489 circuits are all above ground. Thus an open or grounded input will cause the same output as a negative of logic "1" input.

Output Voltage Range	- 0.3 V to $V_{CC} + 0.3$ V

NOTES: 1. All voltage values are with respect to network ground terminal with the REF- and GND terminal pins connected together, unless otherwise noted.

Overview of Operation

The TLC548 is a complete data acquisition system and it includes such functions as an internal System Clock, Sample-and-hold, 8-bit A/D converter, Data register, Control logic, I/O Clock, and a Chip Select (\overline{CS}).

These control inputs and a 3-state data output facilitate serial communications with a microprocessor or minicomputer. A conversion can be completed in a maximum of 17 microseconds, while total access and conversion time is a maximum of 25 microseconds.

The internal System Clock and I/O Clock are used independently and require no special speed or phase relationship. This simplifies the hardware and software control tasks for the device. Because of this independence and the internal generation of the System Clock, the microprocessor and software need only read the previous conversion result and start the conversion with the I/O Clock. The internal System Clock drives the "conversion-crunching" circuitry.

When \overline{CS} is high, the Data Output pin is in a high-impedance condition and the I/O Clock pin is disabled.

This condition allows each of these pins to share a control logic point with its counterpart pin when additional TLC548 devices are used.

Typical Control Sequence

The control sequence has been designed to minimize the time and effort required to initiate conversion and obtain the conversion result.

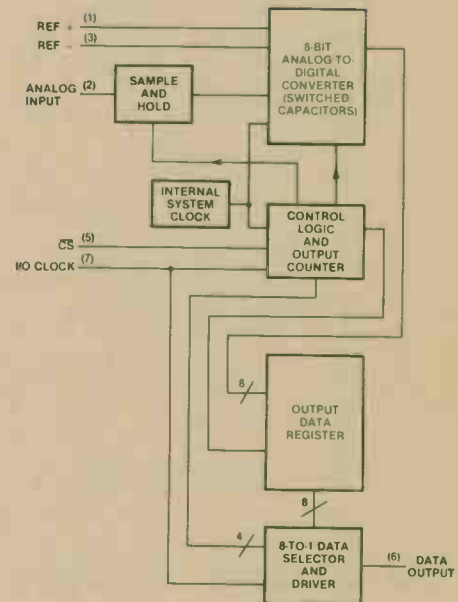

A typical control sequence consists of the following steps.

1. \overline{CS} (Chip Select) is brought low.
After a \overline{CS} transition (from high to low), the internal circuitry of the TLC548 waits for two rising edges and then one falling edge of the internal System Clock before recognizing the transition. This delay minimizes errors caused by noise at the \overline{CS} input. The most-significant bit (MSB) of the result of the previous conversion then appears on the Data Output pin.
2. The negative edges of the first four I/O Clocks shift out the 2nd, 3rd, 4th, and 5th most-significant bits of the result of the previous conversion.
3. The on-chip sample-and-hold begins sampling the analog input after the 4th falling edge.
This operation basically involves the charging of internal capacitors to the voltage level of the analog input.

PIN CONNECTION

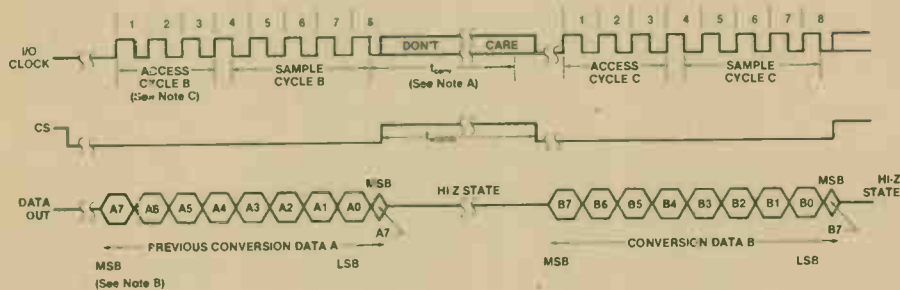

BLOCK DIAGRAM

Typical Control Sequence (cont.)

4. Three more clock cycles are applied to the I/O pin.
The 6th, 7th, and 8th bits of the result of the previous conversion are shifted out on the negative edges of these clock cycles.
5. The 8th and final clock cycle is applied to the I/O Clock pin.
The falling edge of this clock cycle completes the analog sampling process and initiates the hold function.
6. Conversion is performed during the next 36 System Clock cycles.
After the final I/O Clock cycle, \overline{CS} must go high or the I/O Clock must remain low for at least 36 System Clock cycles to allow for the conversion function.

The operating sequence is illustrated below.

Operating Sequence

- NOTES: A. The conversion cycle is initiated with the trailing edge of the 8th I/O Clock pulse after \overline{CS} goes low.
- B. The most-significant bit (MSB) is then placed on the DATA OUT pin after \overline{CS} is brought low. The remaining seven bits (A6-A0) are shifted out on the first seven I/O Clock falling edges.
- C. To minimize errors caused by noise on the \overline{CS} signal, the internal circuitry waits for two rising edges and then one falling edge of the Internal System Clock (1.4 μ s at 2 MHz) after a Chip Select transition before responding to control input signals. Therefore, no attempt should be made to shift out conversion data until the minimum Chip Select setup time has elapsed.

Keeping \overline{CS} Low During Multiple Conversions

\overline{CS} can be kept low during periods of multiple conversions.

If \overline{CS} is taken high, it must remain high until the end of the conversion. Otherwise, a valid falling edge of \overline{CS} will cause a reset condition, aborting the conversion in process.

Stopping an Ongoing Conversion

An ongoing conversion can be stopped and a new conversion started by performing steps 1 thru 6 listed under typical control sequence before the 36 System Clock cycles occur. Such an action yields the conversion result of the previous conversion, not the ongoing conversion.

Starting Conversion at a Specific Time

For certain applications such as strobing, it is necessary to start conversion at a specific point in time. The TLC548 will accommodate these applications.

To trigger a conversion at a specific point in time, control hardware or software must manipulate the 8th I/O clock cycle. The sequence for a conversion at a desired instant is:

- I. The on-chip sample-and-hold operation waits for the falling edge of the 4th I/O clock cycle and begins sampling. The TLC548 follows the analog input but does not hold it yet.
- II. When the 8th I/O clock cycle is high, control hardware or software must keep it high until the desired instant.
- III. At the desired instant, control hardware or software must lower the clock. The falling edge of the 8th I/O clock cycle causes the input to be held and initiates the conversion.

LINCOS (A TO D CONVERTER)

TLC 548 276-1796

Intel 8051/52 Serial Port Interface Operating Sequence

The serial data for the conversion result from the TLC548 enters the microprocessor through the RXD pin. By using the inverted TXD shift clock as an I/O Clock for the TLC548, previous conversion data can be transferred to the microprocessor.

The serial port's Mode 0 state is used to permit 8-bit transmission and reception. The TLC548 sends the most-significant bit of the conversion result first; the serial buffer receives this bit as the least-significant bit. The software then reverses the conversion bits and places them in the proper order.

The timing consists of the following three major phases:

1. After CS goes low, eight I/O Clock cycles access and sample the new analog input. At the same time, I/O Clock falling edges bring out the previous conversion result.
2. Conversion begins when the eighth I/O Clock goes low. Conversion requires 36 internal System Clock cycles after the eighth I/O Clock goes low. The maximum conversion time is 17 microseconds.
3. Eight falling edges of the I/O Clock bring out the previous conversion result.

The Operating Sequence (cont.)

Circuit Timing for Intel 8051/52

Z80A Interface

The Z80A interface is an economical solution, offering efficient control software and communications with the TLC548.

Required Software

A simple program segment that reads in a previous conversion result and starts a conversion is shown below. Placing this program segment in a loop makes it possible to initiate a conversion and read previous conversion results in 111 microseconds.

```

LD C,08H      ; Load bit counter
LD B,00H      ; Initialize result register
OUT (CSLOW),A ; Bring Chip Select low
LOOP  RLC B    ; Rotate result register left
      IN A,[BIT] ; Read in a bit & shift next
      AND 01H  ; Mask off bit 0
      OR  B    ; Or new bit with result
      LD B,A   ; Store in result register
      DEC C   ; Decrement bit counter
      JP NZ,LOOP ; Get another bit if not zero
      OUT (CSHIGH),A ; Bring Chip Select high
    
```

The Operating Sequence

Latching in a low from address bit A0 brings Chip Select low. Execution of an IN instruction causes RD and IORQ to become active, generating one I/O Clock pulse. A data bit is read in just before the falling edge of the I/O Clock pulse. The falling edge shifts out the next data bit.

Sampling of analog input begins at the falling edge of the 4th I/O Clock and continues until the falling edge of the 8th I/O Clock. At that time, conversion begins; conversion requires 17 microseconds.

CS is brought high after the 8th I/O Clock to disable all inputs and outputs so that conversion may proceed undisturbed.

LINC MOS (TIMER)

TLC555 TIMER 276-1718

GENERAL DESCRIPTION

The TLC555 is a monolithic timing circuit fabricated using the Lin CMOS™ process. Due to its high-impedance inputs (typically $10^{12}\Omega$), it is capable of producing accurate time delays and oscillations while using less expensive, smaller timing capacitors. The TLC555 achieves both monostable (using one resistor and one capacitor) and astable (using two resistors and one capacitor) operation. In addition, 50% duty cycle astable operation is possible using only a single resistor and one capacitor. The Lin CMOS™ process allows the TLC555 to operate at frequencies up to 2 MHz and be fully compatible with CMOS, TTL, and MOS logic. It also provides very low power consumption (typically 1 mW at $V_{DD} = 5V$) over a wide range of supply voltages ranging from 2 volts to 18 volts.

Threshold and trigger levels are normally two-thirds and one-third respectively of V_{DD} . These levels can be altered by use of the control voltage terminal. When the trigger input falls below trigger level, the flip-flop is set and the output goes high. If the trigger input is above the trigger level and the threshold input is above the threshold level, the flip-flop is reset and the output is low. The reset input can override all other inputs and can be used to initiate a new timing cycle. When the reset input goes low, the flip-flop is reset and the output goes low. Whenever the output is low, a low impedance path is provided between the discharge terminal and ground.

While the complementary CMOS OUTPUT is capable of sinking over 100 mA and sourcing over 10 mA, the TLC555 exhibits greatly reduced supply current spikes during output transitions.

FEATURES

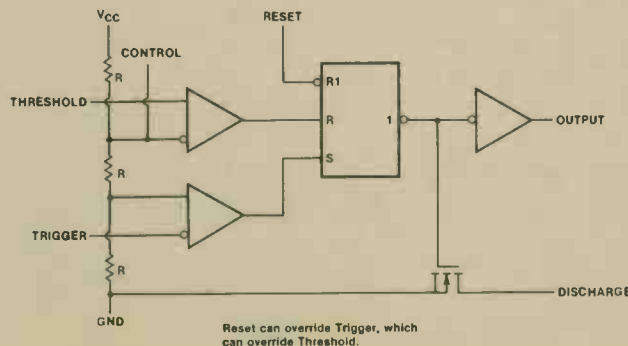

- Very low power consumption (1 mW typical at $V_{DD} = 5V$)
- Capable of very high-speed operation (2 MHz in a stable operation)
- Complementary CMOS output capable of swinging rail to rail
- High output-current capability (sink 100 mA typical) (source 10 mA typical)
- Output fully CMOS, TTL, and MOS-compatible
- Low supply current reduces spikes during output transitions
- High impedance input $10^{12}\Omega$ typical)
- Single supply operation from 2 to 18 volts

QUAD OP AMP

GENERAL DESCRIPTION

The 324 series consists of four independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, dc gain blocks and all the conventional op amp circuits which now can be more easily implemented in single power supply systems. For example, the 324 series can be directly operated off of the standard +5 V_{DC} power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional +15 V_{DC} power supplies.

- Wide power supply range:
Single supply 3 V_{DC} to 30 V_{DC}

- Very low supply current drain (800 μA)—essentially independent of supply voltage (1 mW/op amp at +5 V_{DC})
- Low input biasing current 45 nA_{DC} (temperature compensated)

3-TERMINAL ADJUSTABLE POSITIVE REGULATOR

317T
276-1778

GENERAL DESCRIPTION

The 317T is an adjustable 3-terminal positive voltage regulator capable of supplying in excess of 1.5 A over a 1.2 V to 37 V output range. This device is exceptionally easy to use and requires only two external resistors to set the output voltage.

In addition to higher performance than fixed regulators, the 317T offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Normally, no capacitors are needed unless the device is situated far from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejection ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the 317T is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded.

It will also serve as a simple adjustable switching regulator, programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the 317T can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2 V where most loads draw little current.

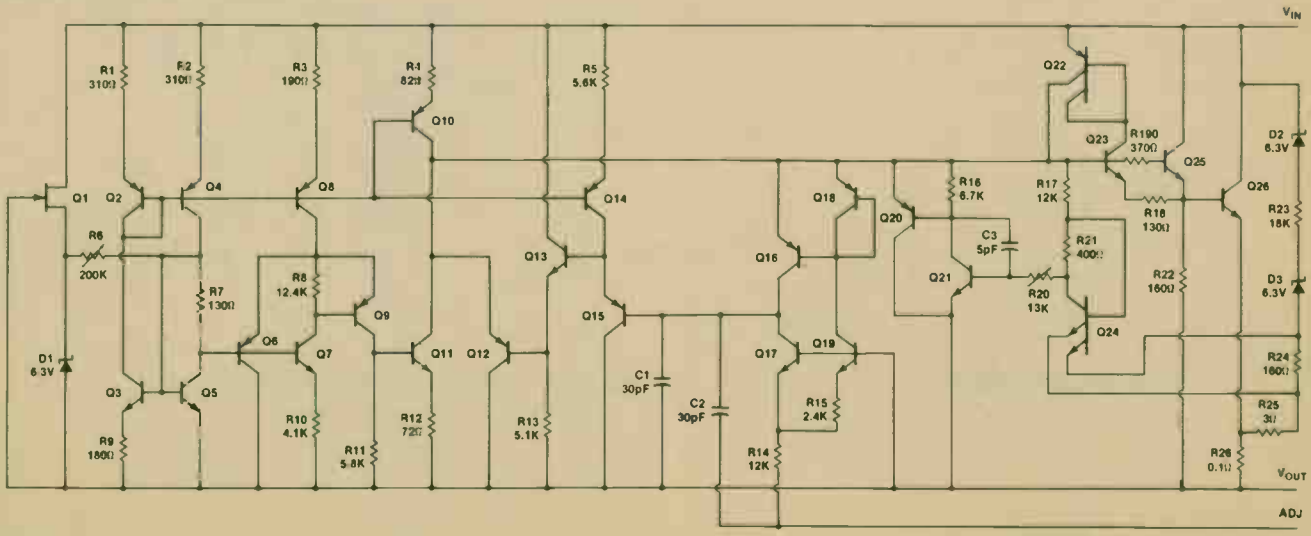

FEATURES

- Adjustable output down to 1.2V
- Guaranteed 1.5A output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- 100% electrical burn-in
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection

5V VOLTAGE REGULATOR

12V VOLTAGE REGULATOR

15V VOLTAGE REGULATOR

GENERAL DESCRIPTION

This series of three terminal regulators is available with several fixed output voltages making them useful in a wide range of applications. One of these is local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow these regulators to be used in logic systems, instrumentation, HiFi, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators these devices can be used with external components to obtain adjustable voltages and currents.

This series will allow over 1.5A load current if adequate heat sinking is provided. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over preventing the IC from overheating.

- Internal thermal overload protection
- No external components required

- Internal short circuit current limit

LED FLASHER/OSCILLATOR

3909
276-1705

GENERAL DESCRIPTION

The 3909 is a monolithic oscillator specifically designed to flash light emitting diodes. By using the timing capacitor for voltage boost, it delivers pulses of 2 or more volts to the LED while operating on a supply of 1.5V or less. The circuit is inherently self-starting, and requires addition of only a battery and capacitor to function as a LED flasher.

It has been optimized for low power drain and operation from weak batteries so that continuous operation life exceeds that expected from battery rating.

Application is made simple by inclusion of internal timing resistors and an internal LED current limit resistor.

Timing capacitors will generally be of the electrolytic type, and a small 3V rated part will be suitable for any LED flasher using a supply up to 6V. However, when picking flash rates, it should be remembered that some electrolytics have very broad capacitance tolerances, for example -20% to +100%.

FEATURES

- Operation over one year from one C size flashlight cell
- Bright, high current LED pulse
- Minimum external parts
- Low voltage operation, from just over 1V to 5V
- Low current drain, averages under 0.5 mA during battery life
- Powerful: as an oscillator directly drives an 8Ω speaker

SSI202
276-1303

5V LOW-POWER DTMF RECEIVER

GENERAL DESCRIPTION

The SSI 202 is a complete Dual Tone Multiple Frequency (DTMF) receiver detecting a selectable group of 12 or 16 standard digits. No front-end pre-filtering is needed. The only externally required components are an inexpensive 3.58-MHz television "colorburst" crystal (for frequency reference) and a bias resistor. Extremely high system density is made possible by using the clock output of a crystal connected SSI 202 receiver to drive the time bases of additional receivers. The SSI 202 uses a monolithic integrated circuit fabricated with low-power, complementary symmetry MOS (CMOS) processing. It requires only a single low tolerance voltage supply.

The SSI 202 employs state-of-the-art circuit technology to combine digital and analog functions on the same CMOS chip using a standard digital semiconductor process. The analog input is pre-processed by 60-Hz reject and band splitting filters and then hard-limited to provide AGC. Eight bandpass filters detect the individual tones. The digital post-processor times the tone durations and provides the correctly coded digital outputs. Outputs interface directly to standard CMOS circuitry, and are three-state enabled to facilitate bus-oriented architectures.

FEATURES

- NO front-end band-splitting filters required

ANALOG IN

This pin accepts the analog input. It is internally biased so that the input signal may be AC coupled. The input may be DC coupled as long as it does not exceed the positive supply. Proper input coupling is illustrated in Fig. 1.

The SSI 202 is designed to accept sinusoidal input wave forms but will operate satisfactorily with any input that has the correct fundamental frequency with harmonics greater than 20 dB below the fundamental.

CRYSTAL OSCILLATOR

The SSI 202 contains an onboard inverter with sufficient gain to provide oscillation when connected to a low-cost television "color-burst" crystal. The crystal oscillator is enabled by tying XEN high. The crystal is connected between XIN and XOUT. A 1 MΩ 10% resistor is also connected between these pins. In this mode, ATB is a clock frequency output. Other SSI 202's may use the same frequency reference by tying their ATB pins to the ATB of a crystal-connected device. XIN and XEN of the auxiliary devices must then be tied high and low respectively. Ten devices may run off a single crystal-connected SSI 202.

IN1633

When tied high, this pin inhibits detection of tone pairs containing the 1633-Hz component. For detection of all 16 standard digits, IN1633 must be tied low.

OUTPUTS D1, D2, D4, D8 and EN

Outputs D1, D2, D4, D8 are CMOS push-pull when enabled (EN high) and open circuited (high impedance) when disabled by pulling EN low. These digital outputs provide the code corresponding to the detected digit in the format programmed by the HEX/B28 pin. The digital outputs become valid after a tone pair has been detected and they are then cleared when a valid pause is timed.

DV and CLRDV

DV signals a detection by going high after a valid tone pair is sensed and decoded at the output pins D1, D2, D4, D8. DV remains high until a valid pause occurs or the CLRDV is raised high, whichever is earlier.

N/C PINS

These pins have no internal connection and may be left floating.

CODE-TO-SPEECH CHIP

CTS256AL2
276-1786

GENERAL DESCRIPTION

The Code-To-Speech chip set consists of two chips: the SPO256A-AL2 (Cat. No. 276-1784), an allophone-base single chip speech synthesizer, and the CTS256A-AL2, an 8-bit microcomputer programmed with a letter-to-sound based algorithm. This chip set translates English characters into LPC synthesized speech sounds.

The SPO256A-AL2 is a standard allophone chip and is based on the SPO256A speech synthesizer. This synthesizer consists of a 10 or 12 pole second-order cascaded LPC filter, a controller, and a 16-Kbit ROM in which 59 allophones (speech sounds) and five pauses are stored.

The CTS256A-AL2 is a device whose on-board ROM is masked with code-to-speech algorithm. This algorithm converts English text (in the form of standard ASCII characters) into SPO256A-AL2 compatible allophone addresses, using letter-to-sound rules.

This chip set delivers highly recognizable speech output from any peripheral device or computer in a flexible and cost effective manner. It can be configured as a dedicated code-to-speech system, as well as add speech output to a user's program running in this CTS256A-AL2 from off-chip Rom. Such user programs are written in PIC7001 assembly language which is 100% compatible with TMS7001 assembly language.

Eproms can be added to improve the pronunciation of certain proper names, acronyms and technical words as well as to store user programs.

CODE-TO-SPEECH ALGORITHM FEATURES:

- BACKSPACE "<", (0B Hex) THE BACKSPACE-KEY CODE ERASES THE INPUT BUFFER ONE CHARACTER AT A TIME, BEGINNING WITH THE LATEST ENTRY.

NOTE: The R/C combination indirectly connected to PIN 14 of the CTS256A-AL2 and to PIN 2, 25 of the SPO256A-AL2 acts as a power-on reset. The requirement to reset the chip-set is a negative-going pulse which remains LO for a minimum of 500 microseconds.

NOTE: A signal (input or output) that is active-LO is designated by its signal name followed by an asterisk (*).

CODE-TO-SPEECH ALGORITHM (Cont'd)

NOTE: The program default address decode of the SPO256A-AL2's ALD* input is 2000H. It is re-definable via the EXCEPTION-WORD or USER eprom. Refer to TABLE 2.

NOTE: MSnibble means most significant nibble, where a nibble is half a byte. MSB means most significant byte; LSB means least significant byte. 'X' stands for the MSnibble of the MSB of the two byte address, and can be 1,2,3,4,5,6,7,8,9,A,B,C,D, or E because an eprom may reside from 1000H to E000H.

NOTE: The term 'delimiter' refers to any punctuation following a word or numerical sequence. These include: , . ; : ! ? spaces and carriage-returns.

CODE-TO-SPEECH ALGORITHM

Upon power-up (or hardware reset) the CTS256A-AL2 determines the system configuration with respect to the following five options:

1- INTERNAL / EXTERNAL RAM SELECTION: (Refer to TABLE 1.)

INTERNAL-RAM mode has an input buffer which accommodates words or phrases that are no greater than 19 characters in length followed by a delimiter; and an output buffer that accommodates an allophone translation of that word or phrase that is no greater than 26 allophone addresses.

Since the translation more often than not results in the output buffer contents consisting of two times that of the input buffer, words no longer than 13 characters in length and numerical sequences of no longer than 4 numbers in length should be used as a rule of thumb. If the output buffer overflows, what has not been spoken yet from the output buffer might be lost, and the BUSY* flag will not necessarily show an input buffer empty status even though the input buffer might be empty. If a translation results in an output buffer overflow, the system reset may have to be used to clear the system.

EXTERNAL-RAM mode can be used to extend the size of the input and output buffers. If no EXCEPTION-WORD or USER eproms are present, the start address default is 3000H. Static RAM can be added in 256 byte contiguous block increments, beginning with a minimum of 512 bytes. The algorithm will find the end address by searching for the first non-RAM location at 256 byte intervals. The search for the end address will not progress beyond 2K bytes.

If an eprom is present, the start and end addresses are re-definable there. Requirements are: minimum start address is 0200H; the start address must begin on a boundary where the LSByte of the address = 00; and without the end address specified in eprom, the maximum valid start address is EE00H.

In any case, 256 bytes are taken for the output buffer; the remainder is the input buffer. (External-Ram used must have an access time of 250 nS or less.)

- 2- **ROM:** A search is made from 1000H to E000H in 4K increments for the 5 byte sequence (80H, 48H, 28H, 58H, 85H) which uniquely identifies the presence of an EXCEPTION-WORD or USER eprom. If neither are present, the system options are set to algorithm default values or can be chosen by the Pin selectable options. If only a USER eprom is present, the system options may be re-defined from the USER eprom; refer to APPENDIX-0. If both USER and EXCEPTION-WORD eproms are present or if only an EXCEPTION-WORD eprom is present, the system option may be re-defined from the EXCEPTION-WORD eprom; refer to APPENDIX-A,B. (External-Ram used must have an access time of 300nS or less.)

Exception-Word Eprom(s): (optional)

Exception-word eprom(s) may reside anywhere within the decodeable addressspace of the CTS256A-AL2 from 1000H to E000H, providing its start address falls on a 4K boundary. The code-to-speech initialization routine will search for its existence which is denoted by a unique 5-byte sequence of numbers (80H, 48H, 28H, 58H, 85H). A few other locations in the primary

Exception-Word Eprom(s): (Cont'd)

exception-word eprom are reserved, and must contain specific sequences of numbers; the remainder are user-defined. Additional exception-word eprom(s) contiguous to the primary exception-word eprom contain no reserved locations. Refer to APPENDIX-A, B for the applicable EXCEPTION-WORD EPROM MEMORY MAP.

User-Eprom(s): (optional)

If a USER eprom is accompanied by an EXCEPTION-WORD eprom, it may reside anywhere. If no EXCEPTION-WORD eprom accompanies it then it may reside anywhere from 1000H to E000H providing its start address falls on a 4K boundary; and it must then begin with the sequence 80H, 48H, 28H, 58H, 85H; and also contain other reserved locations. If an EXCEPTION-WORD eprom is present, the USER's program can even reside in an unused portion of the EXCEPTION-WORD eprom. Refer to APPENDIX-D,E for the applicable USER EPROM MEMORY MAP.

Interaction between a USER program and the code-to-speech algorithm must be controlled in an orderly manner, ie; the user must save the processor status before taking control of the processor for execution of any USER code (except for character string loading operations, which is described next.)

To prepare the code-to-speech algorithm to process and speak, the USER program passes the character string it wants spoken into the Accumulator one character at a time, then calls the routine @SAVE which transfers it into the input buffer. After the character string loading has been completed, the USER code can initiate the speech by calling the @SPEAK routine; assuming that a delimiter followed that character string. After the loaded character string is processed and spoken, program control resumes in the hands of the USER program by the Branch @USERCODE instruction.

No registers used by the code-to-speech algorithm may be disturbed by the USER code during character string loading, (except for the Accumulator).

Prior to the USER code executing anything other than character string loading, all registers used by the code-to-speech algorithm as well as the Stack Pointer and STATUS register are to be saved. These registers must be recovered prior to future character string loading operations; or prior to initiating speech.

Because of masked code-to-speech restrictions within the CTS256A-AL2, Interrupt-1* and Interrupt-3* are not USER accessible. Also, input from the serial port into the USER code can be obtained, but restrictions apply.

Refer to APPENDIX-F for a discussion of the sequence of events and subroutines necessary for USER/CODE-TO-SPEECH interactions as described above.

3- Serial / Parallel Input Interface Selection: (Refer to TABLE 1.)

In the parallel mode, ASCII data is latched by an 74LS374, upon receipt of an Active LO data-valid strobe. This strobe also vectors the algorithm to accept the data via Interrupt-3*, PIN 12 of the CTS256A-AL2. The latch's address default is 200H. It is re-definable from EXCEPTION-WORD or USER eprom. (Refer to TABLE 9 for timing requirements of the parallel port.)

In the serial mode, ASCII data is accepted via the CTS256A-AL2 PIN 16, which is a built-in UART that requires a TTL level signal input. The baud rate is selectable at 50,110,300,1200,2400,4800 and 9600. The other UART parameters are set to algorithm default values, or are hardware selectable via an 74LS373 buffer. The buffer address default is 1000H. The UART parameters as well as the baud rate is re-definable from EXCEPTION-WORD or USER eprom. The algorithm default UART values are: Asynchronous, 7 bits/character, 2 stop bits, and no parity.

In either serial or parallel mode, the input buffer is protected from overflow by a hysteresis subroutine which signals the host when the input buffer is full, and when the input buffer is ready for additional input. Hardware handshaking (BUSY*) is provided to accomplish this signaling of input buffer status.

BUSY* is Active-LO. It toggles LO when the input buffer becomes 87.5% full. In this way the host system may use its discretion to complete that transmission or a part thereof. If the input buffer becomes 100% full, the parallel and serial port interrupts are disabled to prevent input buffer overwrite; and the interrupts are not re-enabled until the input buffer full condition has dissipated. BUSY* will toggle hi when the input buffer becomes 50% empty; at which time the interrupts are enabled if they had been disabled by a 100% full condition. (BUSY* is PIN-3 of the CTS256A-AL2 which is a TTL level output capable of sinking 10 mA maximum.)

MICROCOMPUTER (8-BIT)

CTS256AL2 276-1786

4- Software / Hardware (or Firmware) UART Parameters Selection: (Refer to TABLE 1.)

This hardware option tells the code-to-speech algorithm to use the default UART values, or to find the parameters at the 74LS373 buffer. The buffer address default is 1000H. The UART parameters are re-definable from eeprom, but only if the hardware mode is selected via Pin 9 of the CTS256A-AL2.

5- Any-Delimiter / Carriage-Return-Only Selection: (Refer to TABLE 1.)

In the any-delimiter mode, the code-to-speech algorithm will process and speak words or phrases as soon as they are followed by any delimiter. In the carriage-return-only mode, the algorithm will process and speak words or phrases only after a carriage-return is received as a delimiter. The carriage-return-only mode is meant for use with a slow input device such as a terminal, where the user wishes to buffer-up a complete phrase so that it is spoken with fluency. If the carriage-return-only mode is chosen in conjunction with EXTERNAL-RAM, limit to 160 characters the length of the phrase which is entered before the carriage-return is entered. This allows for a two line phrase to be spoken with fluency while insuring that the 256 byte output buffer should not overflow.

After completion of the initialization the phrase "O.K." is spoken to demonstrate that the system is ready for input, then one of the following two paths is taken dependent upon the system configuration:

- 1: In a 'dedicated code-to-speech system' (ie; USER eeprom is not present), the algorithm idles as long as the input buffer remains empty. Input is via standard ASCII characters. Processing begins with an alphabetical search of the EXCEPTION-WORD eeprom, if it is present. If no exact match for the character string is found, or if an EXCEPTION-WORD eeprom is not present, the algorithm employs a letter-to-sound rule table against which main, right, and left context matches are performed. This results in the translation of a particular word into the proper string of allophone addresses necessary for its pronunciation. This list of allophone address is sent to the SP0256A-AL2 after a carriage-return, or after any delimiter—depending on the mode selected.
- 2: In the 'add speech to USER's program' mode (ie; USER eeprom is present), control of the processor is relinquished to the USER code immediately after the initialization is complete. The USER code may then execute its own code, may pass character strings into the input buffer memory, or may hand-off processor control to the code-to-speech algorithm to speak any previously loaded character strings. If speech is initiated, control returns to the USER code after the last delimited character string in the input buffer has been processed. Refer to APPENDIX-F.

TABLE 5. SERIAL PORT MODE REGISTER

FOR TYPICAL APPLICATIONS USE: MOTOROLA PROTOCOL, ASYNCHRONOUS COMMUNICATION, 7 BITS/CHARACTER, and COMMUNICATION MODE; THE NUMBER OF STOP BITS AND PARITY MODE REMAIN UP TO THE USER.

TABLE 6. SERIAL PORT CONTROL REGISTER / TIMER REGISTER

$$\text{Asynchronous Baud Rate} = \frac{2.5 \text{ MH:}}{64(\text{PL} + 1)(\text{TL} + 1)}$$

$$\text{Isosynchronous Baud Rate} = \frac{2.5 \text{ MH:}}{4(\text{PL} + 1)(\text{TL} + 1)}$$

where: PL = prescale latch value
TL = timer latch value

Example: To program the serial port to operate at 300 baud in the asynchronous mode, the prescaler value is set to 0, and the timer latch value to 81H.

TABLE 9. PARALLEL PORT TIMING REQUIREMENTS:

SETUP TIME, BEFORE DATA CLOCK LO TO HI TRANSITION: MIN. 20 nS. HOLD TIME, BEFORE DATA CLOCK LO TO HI TRANSITION: MIN. 10 nS. WIDTH OF CLOCK LO: MIN. 500 nS.

HOLD OFF TIME, FROM DATA STROBE HI TO LOW TO HI, UNTIL NEXT DATA STROBE HI TO LOW: MIN. 450 uS.

NOTE: The addition of an 74LS74 Flip-Flop as shown on the schematic can be used for parallel port latch handshaking using the Active-LO LATCH-BUSY\$ output. LATCH-BUSY\$ is LO when the latch is full, and it is HI when the latch is empty and available for the next character to be strobed in.

APPENDIX-C

Exception-Word Encoding Scheme

To store a unique word or symbol and its corresponding allophone address string in an efficient and flexible manner, the following encoding format was derived:

<[encoded word or symbol]< = [encoded allophone address(es)]

where: < equals 13H.
 [equals 40H.
] equals 80H.

The first and last byte is 13H. This informs the code-to-speech algorithm that the word or symbol is not a prefix or suffix.

If the word or symbol is an individual letter, then the representation of it between the brackets is an FFH; this includes the value of the left and right brackets.

Otherwise:

- (1) The first letter in the word or symbol is always to be ignored.
- (2) The next letter in the word is represented by the value of the letter from TABLE-7, plus the value of the left bracket “[” which is 40H.
- (3) The following letter(s), if and only if it is not the last letter in the word or symbol, is represented solely by its value from TABLE-7.
- (4) The last letter in the word or symbol is represented by the value of the letter from TABLE-7, plus the value of the right bracket “]” which is 80H.

The allophone address string is encoded in a similar manner:

If only one allophone is used for the pronunciation, it is represented by its value from TABLE-6, plus the value of the right “[” and left “]” brackets which are 40H and 80H respectively.

Otherwise:

- (1) The first allophone is represented by its value from TABLE-8, plus the value of the left bracket “[” which is 40H.
- (2) The following allophone(s), if and only if it is not the last allophone in the string, is represented by its value from TABLE-8.
- (3) The last allophone is represented by its value from TABLE-8 plus the value of the right bracket “]” which is 80H.

Example: To encode “Au” to pronounce as “GOLD”

<[Au]< = [GG2 0W LL DD1]

13,F5,13, 7D, 35,2D,95 ← This line is ready to store in EXCEPTION-WORD epros under the “A” category.

↑ (The encoded string is shown in Hexadecimal notation.)

—Remember, throw away the first letter (in this case an “A”), then find the value of the next letter in TABLE-7 and add 40H plus 80H to it so as to represent the left “[” and right “]” brackets.

SPEECH PROCESSOR

GENERAL DESCRIPTION

The SP0256 (Speech Processor) is a single chip N-Channel MOS LSI device that is able, using its stored program to synthesize speech or complex sounds.

The achievable output is equivalent to a flat frequency response ranging from 0 to 5KHz, a dynamic range of 42dB, and a signal to noise ratio of approximately 35 dB.

The SP0256 incorporates four basic functions:

- A. A software programable digital filter that can be made to model a VOCAL TRACT.
- B. A 16K ROM which stores both data and instructions (THE PROGRAM).
- C. A MICROCONTROLLER which controls the data flow from the ROM to the digital filter, the assembly of the "word settings" necessary for linking speech elements together, and the amplitude and pitch information to excite the digital filter.
- D. A PULSE WIDTH MODULATOR that creates a digital output which is converted to an analog signal when filtered by an external low pass filter.

FEATURES

- Natural Speech
- Wide Operating Voltage
- Simple Interface to Most Microcomputers or Microprocessors

TYPICAL APPLICATION

ALLOPHONE USAGE WITH A MICROPROCESSOR

The SPO256 requires the use of a processor to concatenate the speech sounds to form words.

The SPO256 is controlled using the address pins (A1-A8), ALD (Address Load), and SE (Strobe Enable). The object for controlling the chip is to load an address into it which contains the desired allophone. The speech data for the allophone set is contained within the internal 16 K ROM of the SPO256.

This particular application (Allophone Set) requires only six address pins (A1-A6) to address all the 59 allophones plus five pauses, a total of 64 locations. For simplicity, since only six address pins are needed to address the 64 locations, pins A7 and A8 can be tied low (to ground) and now any further references to the address bus will include A1-A6 and A7=A8=0.

There are two modes available for loading an address into the chip. SE (Strobe Enable) controls the mode that will be used.

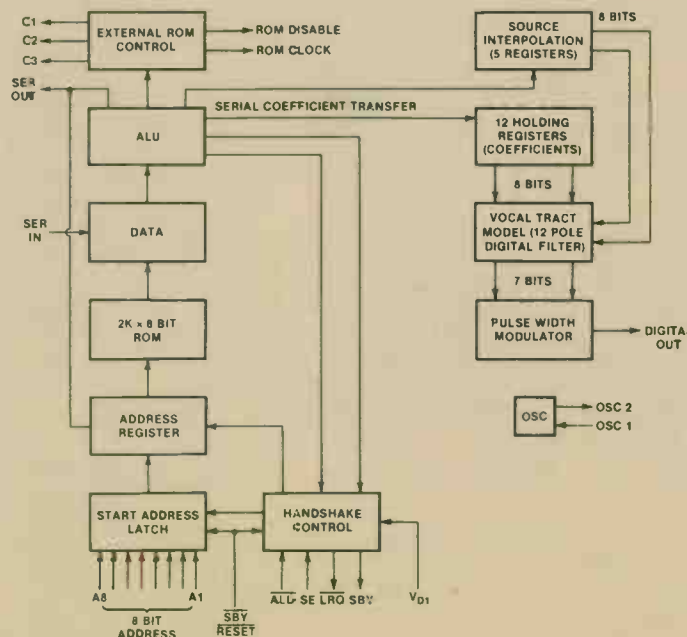

Mode 0 (SE=0) will latch in an address when any one or more of the address pins makes a low to high transition. For example, to load the address one (1), A2 to A6=0 and A1 is pulsed high. To load the address twelve (12 octal), A1=A3=A5=A6=0, A2 and A4 are pulsed high simultaneously. (Note that an address of zero cannot be loaded using this mode).

Mode 1 (SE=1) will latch in an address using the ALD pin. First, setup the desired address on the address bus (A1=A6) and then pulse ALD low. Any address can be loaded using this mode, but certain setup and hold times are required.

Two microprocessor interface pins are available for quick loading of addresses. They are LRQ and SBY. LRQ (Load Request) tells the processor when the input buffer is full. SBY (Stand By) tells the processor that the chip has stopped talking and no new address has been loaded. Either interface pin can be used when concatenating allophones. LRQ is an active low signal, when LRQ goes low it is time to load a new address to the chip. If LRQ is high, then simply wait for it to go low before loading the address. SBY will stay high until an address is loaded, then it will go low and stay low until all the internal instructions (Speech Code) from that one address are completed. Once this signal goes high, it is time to load a new address. Since speech does not require very fast address loading, it would be acceptable to use SBY to interface to the processor.

To end a word using allophones it is necessary to load a pause to complete the word. For example, the word "TWO" can be implemented using the following allophones, TT2-VW2-PA1. PA1 is actually not an allophone but a pause which is needed to end the word.

PIN FUNCTIONS

PIN NUMBER	NAME	FUNCTION
1	V _{SS}	Ground
2	$\overline{\text{RESET}}$	A logic 0 resets that portion of the SP powered by V _{DD} . Must be returned to a logic 1 for normal operation.
3	ROM DISABLE	For use with an external serial speech ROM, a logic 1 disables the external ROM.
4, 5, 6	C1, C2, C3	Output control lines for use with an external serial speech ROM.
7	V _{DD}	Power supply for all portions of the SP except the microprocessor interface logic.
8	SBY	STANDBY. A logic 1 output indicates that the SP is inactive and V _{DD} can be powered down externally to conserve power. When the SP is reactivated by an address being loaded, SBY will go to a logic 0.
9	$\overline{\text{LRQ}}$	LOAD REQUEST. $\overline{\text{LRQ}}$ is a logic 1 output whenever the input buffer is full. When $\overline{\text{LRQ}}$ goes to a logic 0, the input port may be loaded by placing the 8 address bits on A1-A8 and pulsing the $\overline{\text{ALD}}$ output.
10, 11, 13, 14, 15, 16, 17, 18,	A8, A7, A6, A5, A4, A3, A2, A1	8 bit address which defines any one of 256 speech entry points.
12	SER OUT	SERIAL ADDRESS OUT. This output transfers a 16-bit address serially to an external speech ROM.
19	SE	STROBE ENABLE. Normally held in a logic 1 state. When tied to ground, $\overline{\text{ALD}}$ is disabled and the SP will automatically latch in the address on the input bus approximately 1 μ s after detecting a logic 1 on any address line.
20	$\overline{\text{ALD}}$	ADDRESS LOAD. A negative pulse on this input loads the 8 address bits into the input port. The negative edge of this pulse causes $\overline{\text{LRQ}}$ to go high.
21	SER IN	SERIAL IN. This is an 8-bit serial data input from an external speech ROM.
22	TEST	This pin should be grounded for normal operation.
23	VD1	Power supply for the microprocessor interface logic and controller.
24	DIGITAL OUT	Pulse width modulated digital speech output which, when filtered by a 5KHz low pass filter and amplified, will drive a loudspeaker.
25	$\overline{\text{SBY RESET}}$	STANDBY RESET. A logic 0 resets the microprocessor interface logic and the address latches. Must be returned to a logic 1 for normal operation.
26	ROM CLOCK	This is a 1.56MHz clock output used to drive an external serial speech ROM.
27	OSC1	XTAL IN. Input connection for a 3.12MHz crystal.
28	OSC2	XTAL OUT. Output connection for a 3.12MHz crystal

ALLOPHONE SPEECH SYNTHESIS

INTRODUCTION

The allophone speech synthesis technique provides the user with the ability to synthesize an unlimited vocabulary at a very low bit rate. Fifty-nine discrete speech sounds (called allophones) and five pauses are stored at different addresses in the SPO256 internal ROM. Each speech sound was excised from a word and analyzed using linear predictive coding (LPC). Any English word or phrase can be created by addressing the appropriate combination of allophones and pauses. Since there is a total of 64 address locations each requires a 6 bit address. Assuming that speech contains 10 to 12 sounds per second, allophone synthesis requires addressing less than 100 bits per second.

LINGUISTICS

A few basic linguistic concepts will help you start your own library of "allophone words". (See Table 1 for Allophone Dictionary). First, there is no one-to-one correspondence between written letters and speech sounds; secondly, speech sounds are acoustically different depending upon their position within

LINGUISTICS (Continued)

a word; and lastly, the human ear may perceive the same acoustic signal differently in the context of different sounds.

The first point compares to the problem that a child encounters when learning to read. Each sound in a language may be represented by more than one letter and, conversely each letter may represent more than one sound. (See the examples in Table 2.) Because of these spelling irregularities, it is necessary to think in terms of sounds, not letters, when using allophones.

The second, and equally important, point to understand, is that the acoustic signal of a speech sound may differ depending upon its position within a word. For example, the initial K sound in *coop* will be acoustically different from the K's in *keep* and *speak*. The K's in *coop* and *keep* differ due to the influence of the vowels which follow them, and the final K in *speak* is usually not as loud as initial K's.

Finally, a listener may identify the same acoustic signal differently depending on the context in which it is perceived. Don't be surprised, therefore, if an allophone word sounds slightly different when used in various phrases.

PHONEMES OF ENGLISH

The sounds of a language are called phonemes, and each language has a set which is slightly different from that of other languages. Table 3 contains a chart of all the consonant phonemes of English, table 4 all the vowel phonemes.

Consonants are produced by creating an occlusion or constriction in the vocal tract which produces an aperiodic sound source. If the vocal cords are vibrating at the same time, as in the case of the voiced fricatives VV, DH, ZZ, and ZH, (See Table 5) there are two sound sources: one which is aperiodic and one which is periodic.

Vowels are usually produced with a relatively open vocal tract and a periodic sound source provided by the vibrating vocal cords. They are classified according to whether the front or back of the tongue is high or low (See Table 4) whether they are long or short, and whether the lips are rounded or unrounded. In English all rounded vowels are produced in or near the back of the mouth (UW, UH, OW, AO, OR, AW).

Speech sounds which have features in common behave in similar ways. For example, the voiceless stop consonants PP, TT and KK (See Table 3) should be preceded by 50-80 msec of silence, and the voiced stop consonants BB, DD, and GG by 10-30 msec of silence.

ALLOPHONES

Phoneme is the name given to a group of similar sounds in a language. Recall that a phoneme is acoustically different depending upon its position within a word. Each of these positional variants is an allophone of the same phoneme. An allophone, therefore, is the manifestation of a phoneme in the speech signal. It is for this reason that our inventory of English speech sounds is called an allophone set.

HOW TO USE THE ALLOPHONE SET

(See Table 1 for instructions on how to create all the sample words mentioned in this section.) The allophone set (Refer to Table 5) contains two or three versions of some phonemes. It may be necessary to use one allophone of a particular phoneme for word-or-syllable-final position. A detailed set of guidelines for using the allophones is given in Table 5. Note that these are suggestions, not rules.

For example, DD2 sounds good in initial position and DD1 sounds good in final position, as a "daughter" and "collide." One of the differences between the initial and final versions of a consonant is that an initial version may be longer than the final version. Therefore, to create an initial SS, you can use two SSs instead of the usual single SS at the end of a word or syllable, as in "sister." Note that this can be done with TH and FF, and the inherently short vowels (to be discussed below), but with no other consonants. You will want to experiment with some consonant clusters (strings of consonants such as str, cl) to discover which version works best in the cluster. For example, KK1 sounds good before LL as in "clown," and KK2 sounds good before WW as in "square." One allophone of a particular phoneme may sound better before or

SP0256 276-1784

HOW TO USE THE ALLOPHONE SET (Continued)

after back vowels and another before or after front vowels. KK3 sounds good before UH and KK1 sounds good before IY, as in "cookie." Some sounds (PP, BB, TT, DD, KK, GG, CH, and JH) require a brief duration of silence before them. For most of these, the silence has already been added but you may decide you want to add more. Therefore, there are several pauses included in the allophone set varying from 10-200 msec. To create the final sounds in the words "letter" and "little" use the allophone ER and EL.

Remember that you must always think about how a word sounds, not how it is spelled. For example, the NG sound is represented by the letter N in "uncle". And remember that some sounds may not even be represented in words by any letters, as the YY in "computer".

As mentioned earlier there are some vowels which can be doubled to make longer versions for stressed syllables. These are the inherently short vowels IH, EH, EA, EX, AA, and UH. For example, in the word "extent" use one EH in the first syllable, which is unstressed and two EHs in the second syllable which is stressed. Of the inherently long vowels there is one, UW, which has a long and short version. The short one, UW1, sounds good after YY in computer. The long version, UW2, sounds good in monosyllabic words like "two." Included in the vowel set is a group called R-colored vowels. These are vowel + R combinations. For example, the AR in "alarm" and the OR in "score." Of the R-colored vowels there is one, ER, which has a long and short version. The short version is good for polysyllabic words with final ER sounds like "letter," and the long version is good for monosyllabic words like "fir." One final suggestion is that you may want to add a pause of 30-50 msec. between words, when creating sentences, and a pause of 100-200 msec. between clauses.

Note: Every utterance must be followed by a pause in order to make the chip stop speaking the last allophone.

N-CHANNEL ION IMPLANT (SOUND GENERATOR)

AY-3-8910A

276-1787

PROGRAMMABLE SOUND GENERATOR

GENERAL DESCRIPTION

The AY-3-8910A Programmable Sound Generator (PSG) is an LSI circuit which can produce a wide variety of complex sounds under software control. The AY-3-8910A is manufactured in the Microelectronics N-Channel Ion Implant Process. Operation requires a single +5V power supply, a TTL compatible clock, and a microprocessor controller.

The PSG is easily interfaced to any bus-oriented system. Its flexibility makes it useful in applications such as music synthesis, sound effects generation, audible alarms, tone signaling, and home computer usage. In order to generate sound effects while allowing the processor to perform other tasks, the PSG can continue to produce sound after the initial commands have been given by the control processor. The fact that realistic sound production often involves more than one component is satisfied by the three independently controllable analog sound-output channels available in the PSG. These analog sound-output channels can each provide 4 bits of logarithmic digital-to-analog conversion, greatly enhancing the dynamic range of the sounds produced.

All circuit control signals are digital in nature and may be provided directly by a microprocessor/microcomputer. Therefore, one PSG can produce the full range of required sounds with no change in external circuitry. Since the frequency response of the PSG ranges from sub-audible at its lowest frequency to post-audible at its highest frequency, there are few sounds which are beyond reproduction.

PIN FUNCTIONS

DA7-DA0 (Input/Output/High Impedance)

Data/Address Bits 7-0: Pins 30-37

These 8 lines comprise the 8-bit bidirectional bus used by the microprocessor to send both data and addresses to the PSG, and to receive data from the PSG. In the address mode, DA3-DA0 select the internal register address (0-17_h) and DA7-DA4 in conjunction with address inputs $\overline{A9}$ and $\overline{A8}$, form the chip select function. When the high order address bits are "incorrect," the bidirectional buffers are forced to a high impedance state.

Address 9, Address 8

$\overline{A8}$ (input): Pin 25

$\overline{A9}$ (input): Pin 24

High order address bits $\overline{A9}$ and $\overline{A8}$ are fixed to recognize a "01" code. They may be left unconnected, as each is provided with either an on-chip pull-down ($\overline{A9}$) or pull-up ($\overline{A8}$) resistor. In noisy environments, however, it is recommended the $\overline{A9}$ and $\overline{A8}$ be tied to external ground and +5V respectively, if they are not to be used.

RESET (Input): Pin 23

For initialization/power-on purposes, applying a low level input to the RESET pin will reset all registers to 0_h. The RESET pin is provided with an on-chip pull-up resistor.

CLOCK (Input): Pin 22

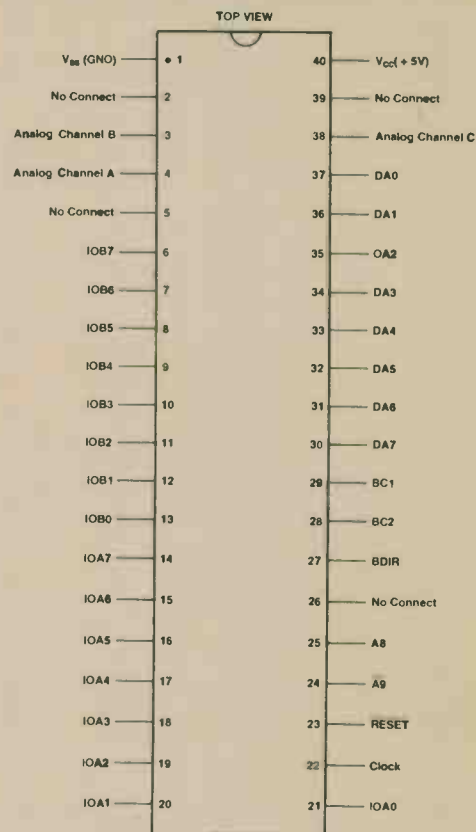

This TTL compatible input supplies the timing reference for the Tone, Noise, and Envelope Generators.

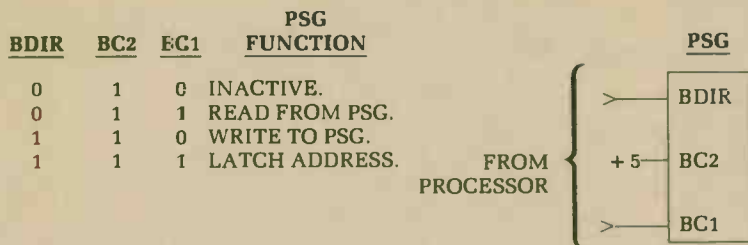

BDIR, BC2, BC1 (Inputs): Pins 27, 28, 29

BUS Direction, BUS Control 2, Bus Control 1

These bus control signals are generated directly by a microprocessor to control all bus operations internal and external to the PSG.

PIN CONNECTION

Analog Channel A, B, C (Outputs): Pins 4, 3, 38

Each of these signals is the output of its corresponding digital to analog converter, and provides 1V peak-peak (max) signal representing the complex sound waveshape generated by the PSG.

Pins 2, 5, 26, 39

These pins are for test purposes only and should be left open. Do not use as tie-points.

V_{CC}: Pin 40

Nominal + 5 Volt power supply to the PSG.

V_{SS}: Pin 1

Ground reference for the PSG.

ARCHITECTURE:

The AY-3-8910A is a register oriented Programmable Sound Generator (PSG). Communication between the processor and the PSG is based on the concept of memory-mapped I/O. Control commands are issued to the PSG by writing to 16 memory-mapped registers. Each of the 16 registers within the PSG is also readable so that the microprocessor can determine, if necessary, present states or stored data values. All functions of the PSG are controlled through the 16 registers which, once programmed, generate and sustain the sounds, thus freeing the system processor for other tasks.

REGISTER ARRAY:

The principal element of the PSG is the array of 16 read/write control registers. These 16 registers look to the CPU as a block of memory and, as such, occupy a 16-word block out of 1,024 possible addresses. The 10 address bits (8 bits on the common data/address bus, and 2 separate address bits) are decoded as follows:

The four low order address bits select one of the 16 registers (R0-R15). The six high order address bits function as chip selects to control the tri-state bidirectional buffers (when the high order address bits are incorrect, the bidirectional buffers are forced to a high impedance state). High order address bits A9, A8 are fixed in the PSG design to recognize a "01" code, high order address bits DA7-DA4 are programmed to recognize only a "0000" code. All addresses are latched internally. This internally latched address is updated and modified on every latch address signal presented to the PSG via the BDIR, BC2, and BC1 inputs. A latched address will remain valid until the receipt of a new address, enabling multiple reads and writes of the same register contents without the need for redundant re-addressing.

Conditioning of the Register Address Latch/Decoder and the Bidirectional Buffers to recognize the bus function required (Inactive, Latch Address, Write Data), is accomplished by the Bus Control Decode block.

N-CHANNEL ION IMPLANT (SOUND GENERATOR)

AY-3-8910A 276-1787

SOUND GENERATING BLOCKS:

The basic blocks in the PSG which produce the programmed sounds include:

Tone Generators	Produce the basic square wave tone frequencies for each channel (A, B, C).
Noise Generator	Produces a pulse width modulated pseudo-random square wave output.
Mixers	Combine the outputs of the Tone Generators and the Noise Generator; per channel (A, B, C).
Envelope Generator	Produces an envelope pattern which can be used to amplitude modulate the output of each Mixer.
Amplitude Control	Provides the D/A Converters with either a fixed or variable amplitude pattern. Fixed amplitude is under direct CPU control. Variable amplitude is accomplished via the output of the Envelope Generator.
D/A Converters	The three D/A Converters each produce a 16 level (max) output signal as determined by the Amplitude Control.

OPERATION

Since all PSG functions are processor controlled by writing to the internal registers, a detailed description of the PSG operation may best be accomplished by relating each PSG function to control of the corresponding register. The function of creating or programming a specific sound effect logically follows the control sequence listed:

<u>Operation</u>	<u>Registers</u>	<u>Function</u>
Tone Generator Control	R0-R5	Program tone periods
Noise Generator Control	R6	Program noise period
Mixer Control	R7	Enable tone and/or noise on selected channels
Amplitude Control	R10-R12	Select fixed or variable (envelope) amplitudes
Envelope Generator Control	R13-R15	Program envelope period and select envelope pattern

Tone Generator Control

(Registers R0, R1, R2, R3, R4, R5)

The frequency of each square wave generated by the three Tone Generators (one each for Channels A, B, and C) is obtained by first dividing the input clock by 16 then by further dividing the result by the programmed 12-bit Tone Period value. Each 12-bit tone period value is obtained by combining the contents of the respective Coarse and Fine Tune registers, as illustrated:

Coarse Tune Register	Channel	Fine Tune Register
R1	A	R0
R3	B	R2
R5	C	R4

The period of the output of the tone generator is therefore determined by:

$$16 \times TP \times P \text{ where } P = \text{the period of the input clock.}$$

NOTE: If the Coarse and Fine Tune registers are both set to 000₈, the resulting period will be minimum, i.e., the generated tone period will be as if the Coarse Tune register was set to 000₈ and the Fine Tune register set to 001₈.

Noise Generator Control

(Register R6)

The frequency of the noise source is obtained by dividing the input clock by 16, then by further dividing the result by the programmed 5-bit Noise Period value. This 5-bit value consists of the lower 5 bits (B4-B0) of register R6, as illustrated:

Mixer Control—I/O Enable

(Register R7)

Register R7 is a multi-function ENABLE register which controls the three Noise/Tone Mixers.

The Mixers, previously described, combine the noise and tone frequencies for each of the three channels. The determination of combining neither/either/both noise and tone frequencies on each channel is made by the state of bits B5-B0 of register R7, as illustrated.

The direction (input or output) of the general purpose I/O ports (I/OA and I/OB) is determined by the state of bits B7 and B6 of R7, as illustrated.

NOTE: Disabling noise and tone does not turn off a channel. Turning a channel off can only be accomplished by writing all zeros into the corresponding Amplitude Control Register.

Amplitude Control

(Registers R10, R11, R12)

The amplitude of the signals generated by each of the three D/A Converters (one each for Channels A, B, and C) is determined by the content of the lower bits (B4–B0) of registers R10, R11, and R12 as illustrated.

These five bits consists of a 1-bit mode select ("M" bit) and a 4-bit "fixed" amplitude level (L3–L0). When the M bit is low, the output level of the analog channel is defined by the 4-bit "fixed" amplitude level of the Amplitude Control Register. This amplitude level is fixed in the sense that the amplitude level is under direct control of the system processor. When the M bit is high, the output level of the analog channel is defined by the 4-bits of the Envelope Generator (bits E3–E0). The amplitude mode bit can also be thought of as an "envelope enable" bit.

Envelope Generator Control

To accomplish the generation of complex envelope patterns, two independent methods of control are provided: first, it is possible to vary the frequency of the envelope using registers R13 and R14; second, the relative shape and cycle pattern of the envelope can be varied using register R15. The following paragraphs explain the details of the envelope control functions, describing first the envelope period control and then the envelope shape/cycle control. (See Figures 1 and 2).

Envelope Period Control

(Registers R13, R14)

The frequency of the envelope is obtained by first dividing the input clock by 256, then by further dividing the result by the programmed 16-bit Envelope Period value. This 16-bit value is obtained by combining the contents of the Envelope Coarse and Fine Tune registers, as illustrated:

16-bit Envelope Period (EP) to Envelope Generator
 Thus the envelope period is given by:
 $256 \times EP \times P$ Where P = period of input clock

NOTE: If the Coarse and Fine Tune registers are both set to 000₈, the resulting period will be minimum, i.e., the generated tone period will be as if the Coarse Tune register was set to 000₈ and the Fine Tune register set to 001₈.

Envelope Shape/Cycle Control

(Register R15)

The Envelope Generator further divides the envelope period by 16, producing a 16-state per cycle envelope pattern as defined by the 4-bit counter output, E3, E2, E1 and E0. The particular shape and cycle pattern of any desired envelope is accomplished by controlling the count pattern of the 4-bit counter. (See Figures 4 and 5).

This envelope shape/cycle control is contained in the lower 4 bits (B3-B0) of register R15. Each of these 4 bits controls a function in the envelope generator, as illustrated:

Envelope Shape/Cycle Control Register (R15)

- Bit 0: HOLD When this is set high (logic 1) the envelope is limited to one cycle, the value of the envelope at the end of the cycle being held.
- Bit 1: ALTERNATE When set high (logic 1) the envelope counter reverses direction at end of each cycle (i.e. performs as an up/down counter).
- Bit 2: ATTACK When set high (logic 1) the envelope counter will count up (attack). When set low (logic 0) the counter will count down (decay).
- Bit 3: CONTINUE When set high (logic 1) the cycle pattern will be defined by the HOLD bit. When set low (logic 0) the envelope counter will reset to 0000 after one cycle, and hold that value.

D/A CONVERTER OPERATION

Since the primary use of the PSG is to produce sound for the non-linear amplitude detection mechanism of the human ear, the D/A conversion is performed in logarithmic steps with a normalized voltage range from 0 to 1 volt. The specific amplitude control of each of the three D/A Converters is accomplished by the three sets of 4 bit outputs of the Amplitude Control block, while the Mixer outputs provide the base signal frequency (Noise and/or Tone). (See Fig. 3).

STATE TIMING

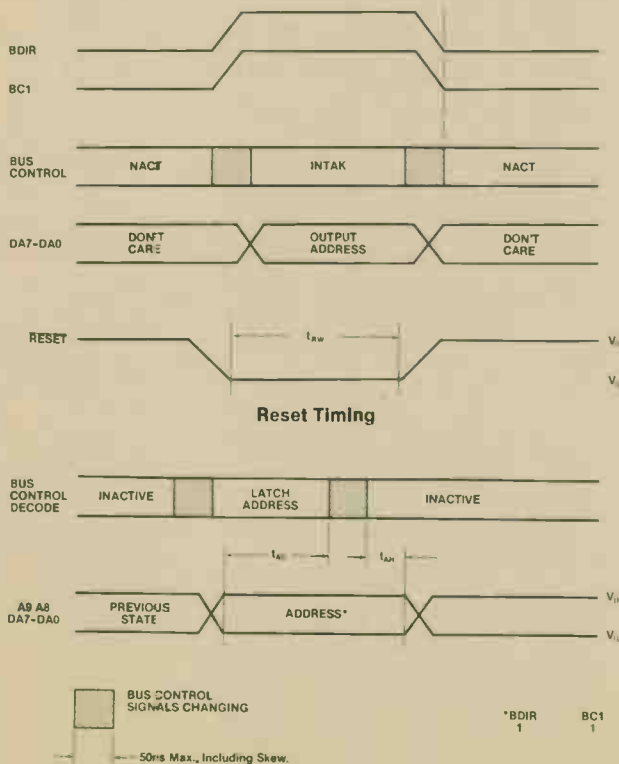

While the state flow for many microprocessors can be somewhat involved for certain operations, the sequence of events necessary to control the PSG is simple and straightforward. Each of the three major state sequences (Latch Address, Write to PSG, and Read from PSG) consists of several operations (indicated below by rectangular blocks), defined by the pattern of bus control signals (BDIR, BC1).

The functional operation and relative timing of the PSG control sequences are described in the following paragraphs.

ADDRESS PSG REGISTER SEQUENCE

The Latch Address sequence is normally an integral part of the write or read sequences, but for simplicity is illustrated here as in individual sequence. Depending upon the processor used, the program sequence will normally require four principal microstates: (1) send NACT (inactive); (2) send INTAK (latch address); (3) put address on bus; (4) send NACT (inactive).

WRITE DATA TO PSG SEQUENCE #1

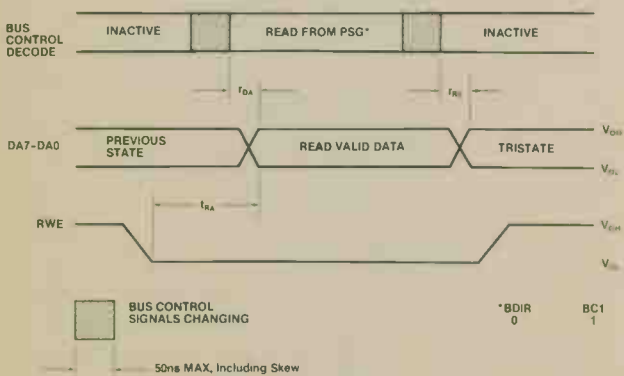

The Write to PSG sequence, which would normally follow immediately after an address sequence, requires four principal microstates: (1) send NACT (inactive); (2) put data on bus; (3) send DWS (write to PSG); (4) send NACT (inactive).

READ DATA FROM PSG SEQUENCE #2

As with the Write to PSG sequence, the Read from PSG sequence would also normally follow immediately after an address sequence. The four principal microstates of the read sequence are: (1) send NACT (inactive); (2) send DTB (read from PSG); (3) read data on bus; (4) send NACT (inactive).

FM RECEIVER

TDA7000
276-1304

GENERAL DESCRIPTION

The TDA7000 is a monolithic integrated circuit for mono FM portable radios, where a minimum on peripheral components is important (small dimensions and low costs).

The IC has an FLL (Frequency-Locked-Loop) system with an intermediate frequency of 70 kHz. The i.f. selectivity is obtained by active RC filters. The only function which needs alignment is the resonant circuit for the oscillator, thus selecting the reception frequency. Spurious reception is avoided by means of a mute circuit, which also eliminates too noisy input signals. Special precautions are taken to meet the radiation requirements.

The TDA7000 includes the R.F. input stage, mixer, local oscillator, I.F. amplifier/limiter, phase demodulator, mute detector and mute switch.

TYPICAL APPLICATION

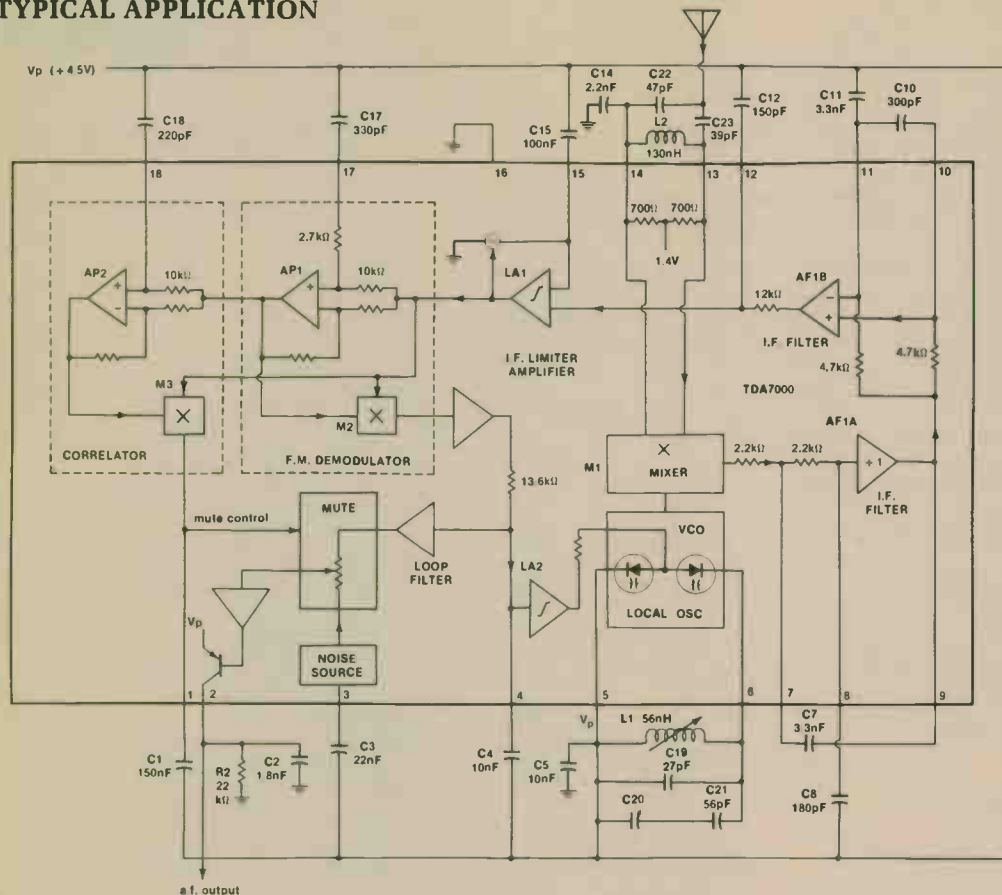

Fig. A The TDA7000 as a variable capacitor tuned f.m. broadcast monitor.

C₇ to C₁₂, C₁₇ and C₁₈:
 Filter and demodulator capacitors. The values shown are for an i.f. of 70 kHz. For other intermediate frequencies, the values of these capacitors must be changed in inverse proportion to the i.f. change.

C₁₄:
 Decouples the reverse r.f. input. It must be connected to the common return via a good quality short connection to ensure a low-impedance path. Inductive or capacitive coupling between C₁₄ and the local-oscillator circuit or i.f. output components must be avoided.

C₁₅:
 Decouples the d.c. feedback for i.f. limiter/amplifier LA1.

C₁₉ and C₂₁:
 Local-oscillator tuning capacitors. Their values depend on the required tuning range and on the value of tuning capacitor C₂₀.

C₂₂, C₂₃, L₁, L₂:
 The values given are for an r.f. bandpass filter with Q = 4 for the European and U.S.A. domestic f.m. broadcast band (87.5 MHz to 108 MHz). For reception of the Japanese f.m. broadcast band (76 MHz to 91 MHz), L₁ must be increased to 78 nH and L₂ must be increased to 150 nH. If stopband attenuation for high level a.m. or tv signals is not required, L₂ and C₂₂ can be omitted and C₂₃ changed to 220 pF.

R₂:
 The load for the audio output current source. It determines the audio output level, but its value must not exceed 22 kΩ for V_p = 4.5 V, or 47 kΩ for V_p = 9 V.

TYPICAL APPLICATIONS

Circuit with variable-capacitance diode tuning

Since it is only necessary to tune the local-oscillator coil, it is very simple to modify the circuit of Fig. A for variable-capacitance diode tuning. The modifications are shown in Fig. B.

Fig. B Variable-capacitance diode tuning for the local oscillator. Additional measures must be taken to ensure temperature stability.

Narrow-band f.m. receiver

The TDA7000 can also be used for reception of narrow-band f.m. signals. In this case, the local-oscillator is crystal-controlled as shown in Fig. C and there is therefore hardly any compression of the i.f. swing by the FLL. The deviation of the transmitted carrier frequency due to modulation must therefore be limited to prevent severe distortion of the demodulated audio signal.

The component values in Fig. C result in an i.f. of 4.5 kHz and an i.f. bandwidth of 5 kHz (Fig. D). If the i.f. is multiplied by N, the values of capacitors C₁₇ and C₁₈ in the all-pass filters and the values of filter capacitors C₇, C₈, C₁₀, C₁₀, C₁₁, and C₁₂ must be multiplied by 1/N. For improved i.f. selectivity to achieve greater adjacent channel attenuation, second-order networks can be used in place of C₁₀ and C₁₁.

In this circuit the detuning noise generator is not used. Since the circuit is mainly for reception of audio signals, the audio output must be passed through a low-pass Chebyshev filter to suppress i.f. harmonics.

The curves numbered 2 were measured with the muting system disabled by injecting about $20 \mu A$ into pin 1 of the TDA7000. The input frequency was 96 MHz modulated with 1 kHz with a deviation of ± 22.5 kHz for the output level curves, and ± 75 kHz for the distortion curve.

IMPORTANT SUGGESTIONS ON THE USE AND REPLACEMENT OF TRANSISTORS

You can use various styles and sizes of transistors in any given circuit application, as long as the electrical characteristics of the device are within the required range of operation. Thus, a tab-type device can be used to replace a TC-3 or TO-66 case device; or a small epoxy-type device can be used in place of TO-5 or other size transistor.

Generally speaking, you must observe the following maximum characteristics of a transistor when contemplating substitution or selection:

- Power dissipation
- Maximum collector current
- Maximum collector-to-emitter voltage
- Maximum collector-to-base voltage
- Maximum emitter-to-base voltage

Also, it is useful to consider the following characteristics for actual circuit operation:

- Gain
- Frequency limitations

Caution: It may be necessary in some cases to adjust bias values to achieve required operation. With tuned circuits, it is a good practice to check alignment after replacing any transistor.

When replacing power transistors, always check driver devices to be sure they are OK. Also, check other circuit components to be sure they were not shorted (or otherwise defective) when the original device failed. If you fail to correct such problems before applying power to the circuit once again, the replacement transistor could easily be permanently damaged. Be sure to use proper heat-sink precautions and use silicon grease to reduce the thermal resistance between the case of the transistor and the heat-sink.

Always observe temperature limitations as specified with transistor ratings.

It almost goes without saying, but let us remind you anyway—

Always observe voltage polarity with all semiconductor devices.

CROSS-REFERENCE/SUBSTITUTION LISTING

Most users of semiconductors realize that it is almost impossible to guarantee absolute equivalents (as in the case of tubes). Thus, the only way to create replacement or cross-reference listings is by carefully evaluating each characteristic of both devices (original transistor and the possible alternate). This is how the Technical Staff of Radio Shack went about preparing the following cross-reference/replacement lists.

IMPORTANT NOTE

We caution you that in many cases the listed cross reference ARCHER device may be different in appearance, size or mounting style. Thus, before beginning replacement or installation procedures, check to be sure you have enough room for proper mounting.

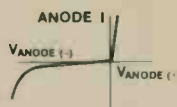

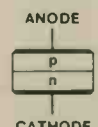

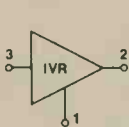

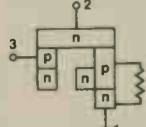

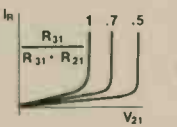

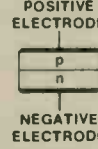

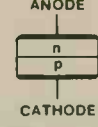

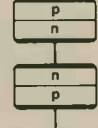

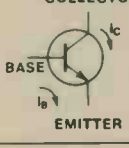

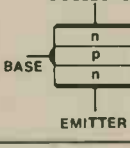

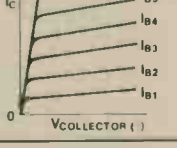

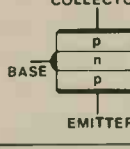

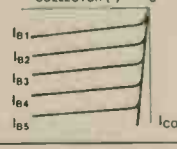

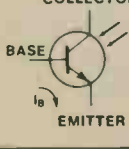

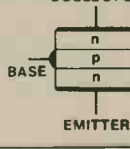

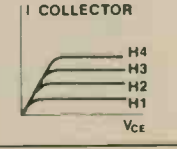

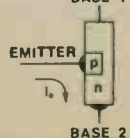

Also, when making substitutions or replacements in radio or high frequency circuitry, it may be necessary to realign tunable circuit elements. This is true even

when making exact replacements (junction capacitances normally vary between devices even from the same production run).

Information contained in this guide is based on the latest available data and is believed to be accurate. Every care has been taken to assure technical accuracy. However, Radio Shack does not assume responsibility for any contingencies of the use of this information. Nor does Radio Shack assume any responsibility for any infringements of patents or other rights of third parties which may result from its use.

When you are looking for a specific number and it does not show up in the following listing—refer to the technical data provided for our line of ARCHER devices. With this information you probably will be able to make a suitable substitution.
